Introduction

The programming language ISLISP is a member of the Lisp family. It is the result of cooperative efforts by the design committee.

The following factors influenced the establishment of design goals for ISLISP:

1. A desire of the international Lisp community to standardize on those features of Lisp upon which there is widespread agreement.
2. The existence of the incompatible dialects Common-LISP, EULISP, LE-LISP, and Scheme (mentioned in alphabetical order).
3. A desire to affirm Lisp as an industrial language.

This led to the following design goals for ISLISP:

1. ISLISP shall be compatible with existing Lisp dialects where feasible.
2. ISLISP shall have as a primary goal to provide basic functionality.
3. ISLISP shall be object-oriented.
4. ISLISP shall be designed with extensibility in mind.
5. ISLISP shall give priority to industrial needs over academic needs.
6. ISLISP shall promote efficient implementations and applications.

The design committee wishes to thank the many specialists who contributed to this document.
Programming Language ISLISP

1 Scope

1. Positive Scope

This document specifies syntax and semantics of the computer programming language ISLISP by specifying requirements for a conforming ISLISP processor and a conforming ISLISP text.

2. Negative Scope

This document does not specify:

(a) the size or complexity of an ISLISP text that exceeds the capacity of any specific data processing system or the capacity of a particular processor, nor the actions to be taken when the corresponding limits are exceeded;
(b) the minimal requirements of a data processing system that is capable of supporting an implementation of a processor for ISLISP;
(c) the method of preparation of an ISLISP text for execution and the method of activation of this ISLISP text, prepared for execution;
(d) the typographical presentation of an ISLISP text published for human reading,
(e) extensions that might or might not be provided by the implementation.

2 Normative references

The following standards contain provisions which, through reference in this text, constitute provisions of this document. At the time of publication, the editions indicated were valid. All standards are subject to revision, and parties to agreements based on this document are encouraged to investigate the possibility of applying the most recent editions of the standards indicated below. Members of IEC and ISO maintain registers of currently valid International Standards.

3 Compliance of ISLISP processors and text

An ISLISP processor complying with the requirements of this document shall

(a) accept and implement all features of ISLISP specified in this document.
(b) reject any text that contains any textual usage which this document explicitly defines to be a violation (see §9).
(c) be accompanied by a document that provides the definitions of all implementation-defined features.
(d) be accompanied by a document that separately describes any features accepted by the processor that are not specified in this document; these extensions shall be described as being “extensions to ISLISP as specified by ISLISP Working Draft 22.0.”

A complying ISLISP text shall not rely on implementation-dependent features. However, a complying ISLISP text may rely on implementation-defined features required by this document.

A complying ISLISP text shall not attempt to create a lexical variable binding for any named constant defined in this document. It is a violation if any such attempt is made.

4 Terms and definitions

For the purposes of this document, the following definitions apply.

4.1 abstract class
a class that by definition has no direct instances

4.2 activation
computation of a function

Note: Every activation has an activation point, an activation period, and an activation end. The activator, which is a function application form prepared for execution, starts the activation at the activation point.

4.3 accessor
association of a reader and a writer for a slot of an instance

4.4 argument position
occurrence of a text unit as an element in a form excluding the first one

4.5 binding
a concept that has both a syntactic and a semantic aspect, where

- syntactically, “binding” describes the relation between an identifier and a binding ISLISP form, and
• semantically, “binding” describes the relation between a variable, its denoting identifier, and an object (or, the relation between a variable and a location)

Note 1: The property of being bound can be checked textually by relating defining and applied identifier occurrences.

Note 2: Semantically, the binding relation might be imagined to be materialized in some entity, the binding. Such a binding entity is constructed at run time and destroyed later, or might have indefinite extent.

4.6 class
object that determines the structure and behavior of a set of other objects, called its instances

Note: The behavior is the set of operations that can be performed on an instance.

4.7 condition
an object that represents a situation that has been (or might be) detected by a running program

4.8 definition point
an identifier represents an ISLISP object starting with its definition point, which is a textual point of an ISLISP text

4.9 direct instance
an instance of a class but not an instance of one of its subclasses

Note: Every ISLISP object is direct instance of exactly one class, which is called “its class”. The set of all direct instances together with their behavior constitute a class.

4.10 dynamic
having an effect that is determined only through program execution and that cannot, in general, be determined statically

4.11 dynamic variable
a variable whose associated binding is determined by the most recently executed active block that established it, rather than statically by a lexically apparent block according to the lexical principle

4.12 evaluation
computation of a form prepared for execution which results in a value and/or a side effect

4.13 execution
a sequence of (sometimes nested) activations

4.14 extension
an implementation-defined modification to the requirements of this document that does not
invalidate any ISLISP text complying with this document (except by prohibiting the use of one or
more particular spellings of identifiers), does not alter the set of actions which are required to
signal errors, and does not alter the status of any feature designated as implementation
dependent

4.15
form
a single, syntactically valid unit of program text, capable of being prepared for execution

4.16
function
an ISLISP object that is called with arguments, performs a computation (possibly having
side-effects), and returns a value

4.17
generic function
function whose application behavior is determined by the classes of the values of its arguments
and which consists – in general – of several methods

4.18
identifier
a lexical element (lexeme) which designates an ISLISP object. In the data structure
representation of ISLISP texts, identifiers are denoted by symbols

4.19
immutable binding
a binding is immutable if the relation between an identifier and the object represented by this
identifier cannot be changed

Note: (It is a violation if there is attempt to change an immutable binding (error-id.
immutable-binding))

4.20
immutable object
an object which is not subject to change, either because no operator is provided that is capable
of effecting such change, or because some constraint exists which prohibits the use of an operator
that might otherwise be capable of effecting such a change

Note: Except as explicitly indicated otherwise, a conforming processor is not required to detect
attempts to modify immutable objects; the consequences are undefined if an attempt is made to modify
an immutable object.

4.21
implementation defined
a feature, possibly differing between different ISLISP processors, but completely defined for every
processor

4.22
implementation dependent
a feature, possibly differing between different ISLISP processors, but not necessarily defined for
any particular processor

Note: A conforming ISLISP text must not depend upon implementation-dependent features.
4.23

*inheritance*

relation between a class and its superclass which maps structure and behavior of the superclass onto the class

**Note:** ISLISP supports a restricted form of multiple inheritance; *i.e.*, a class may have several direct superclasses at once

4.24

*instance (of a class)*
either a direct instance of a class or an instance of one of its subclasses

4.25

*literal*
an object whose representation occurs directly in a program as a constant value

4.26

*metaclass*
a class whose instances are themselves classes

4.27

*method*
case of a generic function for a particular parameter profile, which defines the class-specific behavior and operations of the generic function

4.28

*object*
anything that can be created, destroyed, manipulated, compared, stored, input, or output by the ISLISP processor

**Note 1:** In particular, functions are ISLISP objects.

**Note 2:** Objects that can be passed as arguments to functions, can be returned as values, can be bound to variables, and can be part of structures, are called *first-class objects.*

4.29

*operator*
the first element of a compound form, which is either a reserved name that identifies the form as a special form, or the name of a macro, or a lambda expression, or else an identifier in the function namespace

4.30

*oparator position*
occurrence of a text unit as the first element in a form

4.31

*parameter profile*
parameter list of a method, where each formal parameter is accompanied by its class name. If a parameter is not accompanied by a class name, it belongs to the most general class

4.32

*place*
a location where objects can be stored and retrieved later

**Note:** Places are designated by forms which are permitted as the first argument of `setf`. If used this
way an object is stored in the place. If the form is not used as first argument of \texttt{setf} the stored object is retrieved. The cases are listed in the description of \texttt{setf}.

4.33

\textit{process}

the execution of an ISLISP text prepared for execution

4.34

\textit{processor}

a system or mechanism, that accepts an ISLISP text (or an equivalent data structure) as input, prepares it for execution, and executes the result to produce values and side effects

4.35

\textit{program}

an aggregation of expressions to be evaluated, the specific nature of which depends on context.

Note: Within this document, the term “program” is used only in an abstract way; there is no specific syntactic construct that delineates a program.

4.36

\textit{scope (of an identifier)}

the textual part of a program where the meaning of that identifier is defined; \textit{i.e.}, there exists an ISLISP object designated by this identifier.

4.37

\textit{slot}

a named component of an instance which can be accessed using the slot accessors. The structure of an instance is defined by the set of its slots

4.38

\textit{text}

da text that complies with the requirements of this document (\textit{i.e.}, with the syntax and static semantics of ISLISP) An ISLISP text consists of a sequence of toplevel forms.

4.39

\textit{toplevel form}

any form that either is not nested in any other form or is nested only in \texttt{progn} forms

4.40

\textit{toplevel scope}

the scope in which a complete ISLISP text unit is processed

4.41

\textit{writer}

a method associated with a slot of a class, whose task is to bind a value with a slot of an instance of that class

5 Notation and conventions

For a clear definition of, and a distinction between, syntactic and semantic concepts, several levels of description abstraction are used in the following.
There is a correspondence from ISLISP textual units to their ISLISP data structure representations. Throughout this document the text and the corresponding ISLISP objects (data structures) are addressed simultaneously. ISLISP text can be seen as an external specification of ISLISP data structures. To distinguish between the two representations different concepts are used. When textual representation is discussed, textual elements (such as identifiers, literals, and compound forms) are used; when ISLISP objects are discussed, objects (such as symbols and lists) are used.

The constituents of ISLISP text are called forms. A form can be an identifier, a literal, or a compound form. A compound form can be a function application form, a macro form, a special form, or a defining form.

An identifier is represented by a symbol. A compound form is represented by a non-null list. A literal is represented by neither a symbol nor a list, and so is neither an identifier nor a compound form; for example, a number is a literal.

An object is prepared for execution; this might include transformation or compilation, including macro expansion. The method of preparation for execution and its result are not defined in this document (with exception of the violations to be detected). After successful preparation for execution the result is ready for execution. The combination of preparation for execution and subsequent execution implements ISLISP's evaluation model. The term “evaluation” is used because ISLISP is an expression language—each form has a value which is used to compute the value of the containing form. The results obtained when an entity is prepared for execution are designated throughout this document by the construction “prepared entity”; e.g., “prepared form,” “prepared special form.”

Example: A “cond special form” becomes a “prepared cond” by preparation for execution.

In the examples, the metasymbol “⇒” designates the result of an actual evaluation. For example:

\[ (+ 3 4) \Rightarrow 7 \]

The metasymbol “⇒” identifies the class that results from the evaluation of a form having a given pattern. For example:

\[ (+ \, i_1 \, i_2) \Rightarrow \text{<integer>} \]

Given a form pattern (usually defined by its constant parts, the function name or special operator), ⇒ relates it to the class to which the result of the evaluation of all matching forms belong.

Form patterns or forms which are equivalent are related by \( \equiv \).

The following notational conventions for form patterns are used:

\[
(f\, name \, argument*) \Rightarrow result\,-\,class \quad \text{\textit{f kind}}
\]

In this notation, words written in \textit{italics} are non-terminal (pattern variables). \textit{f-name} is always terminal. Specific function names, special operators, defining form names, or generic function names are always presented.

PUBLIC DOMAIN

7
An underlined term (like the \textit{name} in a defining form) in this notation, indicates an expression that is not evaluated. If a form might or might not be evaluated (like one of the \textit{then-form} or \textit{else-form} in an if), this is indicated explicitly in the text.

Class names are uniformly denoted as follows: \textit{<class-name>}. For example, \textit{<list>} is the name of a class; this is usually spoken aloud as “list class.”

Notes, appearing as \textbf{Note}: note-text, in this document have no effect on the language. They are for better understanding by the human reader.

Regarding the pattern variables and the extensions of above, the following conventions are also adopted:

\begin{align*}
\textit{term}^+ & \text{ denotes one or more occurrences of } \textit{term}; \\
\textit{term}^* & \text{ denotes zero or more occurrences of } \textit{term}; \\
[\textit{term}] & \text{ denotes at most one occurrence of } \textit{term}, \text{ commonly one says that } \textit{term} \text{ is optional}; \\
\{\textit{term}_1 \textit{term}_2 \ldots\} & \text{ denotes grouping of } \textit{terms}. \\
\textit{term}_1 | \textit{term}_2 | \ldots & \text{ denotes grouping of alternative } \textit{terms}.
\end{align*}

The following naming conventions are used to denote forms whose arguments obey the respective class restrictions:

\begin{align*}
\textit{array}, \textit{array}_1, \ldots \textit{array}_j, \ldots & \quad \textit{<basic-array>} \\
\textit{cons}, \textit{cons}_1, \ldots \textit{cons}_j, \ldots & \quad \textit{<cons>} \\
\textit{list}, \textit{list}_1, \ldots \textit{list}_j, \ldots & \quad \textit{<list>} \\
\textit{obj}, \textit{obj}_1, \ldots \textit{obj}_j, \ldots & \quad \textit{<object>} \\
\textit{sequence}, \textit{sequence}_1, \ldots \textit{sequence}_j, \ldots & \quad \textit{<basic-vector>} \text{ or } \textit{<list>} \text{ (see [25])} \\
\textit{stream}, \textit{stream}_1, \ldots \textit{stream}_j, \ldots & \quad \textit{<stream>} \\
\textit{string}, \textit{string}_1, \ldots \textit{string}_j, \ldots & \quad \textit{<string>} \\
\textit{char}, \textit{char}_1, \ldots \textit{char}_j, \ldots & \quad \textit{<character>} \\
\textit{function}, \textit{function}_1, \ldots \textit{function}_j, \ldots & \quad \textit{<function>} \\
\textit{class}, \textit{class}_1, \ldots \textit{class}_j, \ldots & \quad \textit{<class>} \\
\textit{symbol}, \textit{symbol}_1, \ldots \textit{symbol}_j, \ldots & \quad \textit{<symbol>} \\
\textit{x}, \textit{x}_1, \ldots \textit{x}_j, \ldots & \quad \textit{<number>} \\
\textit{z}, \textit{z}_1, \ldots \textit{z}_j, \ldots & \quad \textit{<integer>}
\end{align*}

In this document the conventions detailed below are used, except where noted:
\(\neg p\) Predicates—sometimes called “boolean functions”—usually have names that end in a \(\neg p\). Usually every class \(<\text{name}>\) has a characteristic function, whose name is built as \text{name} \(\neg p\) if \text{name} is hyphenated (generic-function \(\neg p\)), or \text{name} \(p\) if \text{name} is not hyphenated (symbol1p). Note that not all functions whose names end with “\(p\)” are predicates.

\textbf{create-} Usually a built-in class \(<\text{name}>\) has a constructor function, which is called \textbf{create-name}.

\textbf{def} This is used as the prefix of the defining operators.

\textbf{set-} Within this document, any functions named \textbf{set-name} are writers for a place, for which there is a corresponding reader named \textbf{name}.

For any kind of entity in the language, the phrase “\textit{entity-kind} \textbf{name}” refers to the entity of kind \textit{entity-kind} denoted by \textbf{name}. For example, the phrases “function \textbf{name},” “constant \textbf{name},” or “class \textbf{name}” respectively mean the function, constant, or class denoted by \textbf{name}.

## 6 Lexemes

An ISLISP text is built up from lexemes. Lexemes are built up from at least the following characters (see §20):

\[
\begin{align*}
A & B C D E F G H I J K L M N O P Q R S T U V W X Y Z \\
a & b c d e f g h i j k l m n o p q r s t u v w x y z \\
0 & 1 2 3 4 5 6 7 8 9 + - < > / * & = . ? _ ! $ % : @ [ ] - { } - #
\end{align*}
\]

Additional characters are implementation-defined.

The following characters are individual lexemes (see §16 and §21.1):

\[
( ) , \ ' \ ' \ ' \ '
\]

The following character tuples (where \(n\) is a sequence of digits) are individual lexemes (see §12.7, §16, and §22.1):

\[
# ' #( , 0 #B #b #0 #o #X #x #h a #nA
\]

The textual representations of symbols (see §18), numbers (see §19), characters (see §20), and strings (see §24) are lexemes.

\(\backslash\) (single escape) and \(\backslash\) (multiple escape) are special characters. They may occur in some lexemes (identifiers and string literals).

Other lexemes are separated by delimiters. Delimiters are separators along with the following characters:

\[
( ) \ ' , \ '
\]

The effect of delimiting is disestablished inside a string (see §24) or inside a corresponding pair of multiple escape characters (see §18) or for the character immediately following \#\(\backslash\).

\textbf{PUBLIC DOMAIN}
6.1 Separators

Separators are as follows: blank, comments, newline, and an implementation-defined set of characters, (e.g., tabs). Separators have no meaning and can be replaced by each other without changing the meaning of the ISLISP text.

6.2 Comments

The character semicolon (;) is the comment begin character. That is, the semicolon and all the characters up to and including the end-of-line form a comment.

A character sequence beginning with #| and ending with |# is a comment. Such comments may be nested.

Being a separator, a comment cannot occur inside a lexeme.

7 Textual representation

The textual representation of an object is machine independent. The following are some of the textual representations of the ISLISP objects. This representation is readable by the read function. Lexemes are described in §6.

**Null** The object nil is the only object whose class is `<null>`. Upon input, it may be written as nil or (). It is implementation defined whether nil prints as nil or ().

**List** Proper lists are those lists terminated by nil. Usually they are denoted as `(obj1 obj2 ... objn)`. A dotted list (i.e., a list whose last tail is not nil) appears as `(obj1 obj2 ... objn . objn+1)`.

**Character** An instance of the `<character>` class is represented by `#\?`, where “?” is the character in question. There are two special standard characters that are not represented in this way, namely `newline` and `space`, whose representations are `#\newline` and `#\space`, respectively.

**Cons** A cons is expressed as `(car . cdr)`, where the car and cdr are objects.

**Integer** An integer (radix 10) is represented as a sequence of digits optionally preceded by a + or - sign. If the number is represented in binary radix (or in octal or hexadecimal) then the textual representation is preceded by `#b` (or `#o` or `#x`, respectively).

**Float** A floating point number is written in one of the following formats:

\[
\begin{align*}
\text{<?dd \ldots d dd \ldots d} \\
\text{<?dd \ldots d dd \ldots \text{dE}[<s]dd \ldots d} \\
\text{<?dd \ldots d dd \ldots \text{dE}[<s]dd \ldots d} \\
\text{<?dd \ldots d dd \ldots \text{dE}[<s]dd \ldots d} \\
\text{<?dd \ldots \text{dE}[<s]dd \ldots d} \\
\text{<?dd \ldots \text{dE}[<s]dd \ldots d}
\end{align*}
\]

where s is either “+” or “-”, and d is one of “0”–“9”. For example: 987.12, +12.5e-13, -1.5e12, 1E32\(^1\).

\(^1\)This number, although belonging to the set of natural numbers, usually is considered as only a floating point number because of its representation.
Vector A vector of class `<general-vector>` is written as `#(obj1 ... objn)`.

Array An array of class `<general-array>` or `<general-vector>` can be written on input as `#na` (where `n` is an integer indicating the number of dimensions of the array) followed by a nested structure of sequences denoting the contents of the array. This structure is defined as follows. If `n = 1` the structure is simply `(obj1 ... objn)`. If `n > 1` and the dimensions are `n1 n2 ...`, the structure is `(str1 ... strn1)`, where the `str` are the structures of the `n1` subarrays, each of which has dimensions `(n2 ...`). As an example, the representation of `(create-array '(2 3 4) 5)` is as follows:

```
#3a((5 5 5) (5 5 5) (5 5 5) (5 5 5) (5 5 5) (5 5 5))
```

On output (see format), arrays of class `<general-vector>` will be printed using `#( ... )` notation.

String A string is represented by the sequence of its characters enclosed in a pair of `'s. For example: "abc". Special characters are preceded with a backslash as an escape character.

Symbol A named symbol is represented by its print name. Vertical bars (|) might need to enclose the symbol if it contains certain special characters; see §18. The notation, if any, used for unnamed symbols is implementation defined.

There are objects which do not have a textual representation, such as a class or an instance of the `<function>` class.

8 Reserved identifiers

Symbols whose names contain a colon (:) or an ampersand (&) are reserved and may not be used as identifiers. Symbols whose names start with colon (:) are called keywords.

9 Errors

An error is a situation arising during execution in which the processor is unable to continue correct execution according to the semantics defined in this document. The act of detecting and reporting such an error is called signaling the error.

A violation is a situation arising during preparation for execution in which the textual requirements of this document are not met. A violation shall be detected during preparation for execution.

9.1 Classes of error specification

The wording of error specification in this document is as follows:

(a) "an error shall be signaled"

An implementation shall detect an error of this kind no later than the completion of execution of the form having the error, but might detect them sooner (e.g., when the code is being prepared for execution).
Evaluation of the current form shall stop. If no active handler is established by 
\texttt{with\-handler}, it is implementation defined whether the entire running process exits, a 
debugger is entered, or control is transferred elsewhere within the process.

(b) “the consequences are undefined”

This means that the consequences are unpredictable. The consequences may range from 
harmless to fatal. No conforming \texttt{ISLISP} text may depend on the results or effects. A 
conforming \texttt{ISLISP} text must treat the consequences as unpredictable. In places where 
“must,” “must not,” or “may not” are used, then this is equivalent to stating that “the 
consequences are undefined” if the stated requirement is not met and no specific 
consequence is explicitly stated. An implementation is permitted to signal an error in this 
case.

For indexing and cross-referencing convenience, errors in this document have an associated error 
identification label, notated by text such as “\texttt{(error-id. \textit{sample})}.” The text of these labels has no 
formal significance to \texttt{ISLISP} texts or processors; the actual class of any object which might be 
used by the implementation to represent the error and the text of any error message that might 
be displayed is implementation dependent.

9.2 Pervasive error types

Most errors are described in detail in the context in which they occur. Some error types are so 
pervasive that their detailed descriptions are consolidated here rather than repeated in full detail 
upon each occurrence.

1. Domain error: an error shall be signaled if the object given as argument of a standard 
function for which a class restriction is in effect is not an instance of the class which is 
required in the definition of the function (error-id. \texttt{domain\-error}).

2. Arity error: an error shall be signaled if a function is activated with a number of 
arguments which is different than the number of parameters as required in the function 
definition (error-id. \texttt{arity\-error}).

3. Undefined entity error: an error shall be signaled if the entity denoted by an identifier does 
not exist when a reference to that entity is made (error-id. \texttt{undefined\-entity}). Two 
commonly occurring examples of this type of error are \texttt{undefined\-function} and 
\texttt{unbound\-variable}.

This list does not exhaust the space of error types. For a more complete list, see §29.4.

10 Classes

In \texttt{ISLISP}, data types are covered by the class system. A \textbf{class} is an object that determines the 
structure and behavior of a set of other objects, which are called its \textbf{instances}. Every \texttt{ISLISP} 
object is an instance of a class. The behavior is the set of operations that can be performed on 
an instance.

A class can inherit structure and behavior from other classes. A class whose definition refers to 
other classes for the purpose of inheriting from them is said to be a \textbf{subclass} of each of those
classes. The classes that are designated for purposes of inheritance are said to be superclasses of the inheriting class.

A class can be named by an identifier. For example, this identifier can be used as a parameter specializer in method definitions. The class special form can be used to refer to the class object corresponding to its name.

A class \( C_1 \) is a direct superclass of a class \( C_2 \) if \( C_2 \) explicitly designates \( C_1 \) as a superclass in its definition, or if \( C_1 \) is defined by this document to be a direct superclass of \( C_2 \) (for example, by use of a directed arrow from \( C_1 \) to \( C_2 \) in Figure 1). In this case \( C_2 \) is a direct subclass of \( C_1 \). A class \( C_n \) is a superclass of \( C_1 \) if there exists a series of classes \( C_2, \ldots, C_{n-1} \) such that \( C_{i+1} \) is a direct superclass of \( C_i \) for \( 1 \leq i < n \). In this case, \( C_1 \) is a subclass of \( C_n \). A class is considered neither a superclass nor a subclass of itself. That is, if \( C_1 \) is a superclass of \( C_2 \), then \( C_1 \neq C_2 \). The set of classes consisting of some given class \( C \) along with all of its superclasses is called “\( C \) and its superclasses.”

If a user-defined class \( C \) inherits from two classes, \( C_1 \) and \( C_2 \), the only superclasses that \( C_1 \) and \( C_2 \) may have in common are \(<standard-object>\) or \(<object>\). This allows a restricted form of multiple inheritance.

Every ISLISP object is a direct instance of exactly one class which is called “its” class.

An instance of a class is either a direct instance of that class or an instance of one of its subclasses.

Classes are organized into a directed acyclic graph defined by the subclass relation. The nodes are classes and there is an edge from \( C_1 \) to \( C_2 \) if \( C_2 \) is direct subclass of \( C_1 \). This graph is called the inheritance graph. It has as root the class \(<object>\), the only class with no superclass. Therefore it is the superclass of every class except itself. The class named \(<standard-object>\) is an instance of the class \(<standard-class>\) and is a superclass of every class that is an instance of \(<standard-class>\) except itself.

Each class has a class precedence list, which is a total ordering on the set of the given class and its superclasses. The total ordering is expressed as a list ordered from most specific to least specific. The class precedence list is used in several ways. In general, more specific classes can shadow, or override, features that would otherwise be inherited from less specific classes. The method selection and combination process uses the class precedence list to order methods from most specific to least specific.

10.1 Metaclasses

Classes are represented by objects that are themselves instances of classes. The class of the class of an object is termed the metaclass of that object. The term metaclass is used to refer to a class that has instances that are themselves classes.

The metaclass determines the form of inheritance used by the classes that are its instances and the representation of the instances of those classes.

The ISLISP Object System provides the following predefined metaclasses:

- The class \(<standard-class>\) is the default class of classes defined by \defclass\.
- The class \(<built-in-class>\) is the class whose instances are classes that have special
Figure 1. Class Inheritance
implementations or restricted capabilities. For example, it is not possible to define subclasses of a built-in class.

10.2 Predefined classes

The following classes are primitive classes in the class system (i.e., predefined classes that are not metaclasses):

<arithmetic-error> <floating-point-overflow> <simple-error>  
<basic-array> <function> <standard-generic-function>  
<basic-array*> <general-array*> <standard-object>  
<basic-vector> <general-vector> <storage-exhausted>  
<character> <generic-function> <stream>  
<cons> <integer> <stream-error>  
<control-error> <list> <string>  
<division-by-zero> <null> <symbol>  
<domain-error> <number> <unbound-variable>  
<end-of-stream> <object> <undefined-entity>  
<error> <parse-error> <undefined-function>  
<float> <program-error>  
<floating-point-overflow> <serious-condition>

The classes <standard-class> and <built-in-class> are predefined metaclasses.

A user-defined class, defined by defclass, must be implemented as an instance of <standard-class>. A predefined class can be implemented either as an instance of <standard-class> (as if defined by defclass) or as an instance of <built-in-class>.

Figure 1 shows the required inheritance relationships among the classes defined by ISLISP. For each pair of classes C1 and C2 in this figure, if C1 is linked directly by an arrow to C2, C1 is a direct superclass of C2 (and C2 is a direct subclass of C1). Additional relationships might exist, subject to the following constraints:

1. It is implementation defined whether <standard-generic-function> is a subclass of the class <standard-object>.

2. Except as described in Figure 1 and the above constraint on <standard-generic-function>, no other subclass relationships exist among the classes defined in this document. However, additional implementation-specific subclass relationships may exist between implementation-specific classes and classes defined in this document.

3. The class precedence list for <null> observes the partial order <null>, <symbol>, <list>, <object>.

4. Users may define additional classes using defclass.

A built-in class is one whose instances have restricted capabilities or special representations. The defclass defining form must not be used to define subclasses of a built-in class. An error shall be signaled if create is called to create an instance of a built-in class.
A standard class is an instance of `<standard-class>`, and a built-in class is an instance of `<built-in-class>`.

A standard class defined with no direct superclasses is guaranteed to be disjoint from all of the classes in the figure, except for the classes named `<standard-object>` and `<object>`.

The class `<function>` is the class of all functions. The class `<standard-generic-function>` is the default class of all generic functions.

## 10.3 Standard classes

### 10.3.1 Slots

An object that has `<standard-class>` as its metaclass has zero or more named slots. The slots of an object are determined by the class of the object. Each slot can hold one object as its value. The name of a slot is an identifier.

When a slot does not have a value, the slot is said to be **unbound**. The consequences are undefined if an attempt is made to retrieve the value of an unbound slot.

Storing and retrieving the value of a slot is done by generic functions defined by the `defclass` defining form.

All slots are local; i.e., there are no shared slots accessible by several instances.

A class is said to **define** a slot with a given name when the `defclass` defining form for that class contains a slot specifier with that name. Defining a slot does not immediately create a slot; it causes a slot to be created each time an instance of the class is created.

A slot is said to be **accessible** in an instance of a class if the slot is defined by the class of the instance or is inherited from a superclass of that class. At most one slot of a given name can be accessible in an instance. A detailed explanation of the inheritance of slots is given in the section §15.13.

### 10.3.2 Creating instances of classes

The generic function `create` creates and returns a new instance of a class. ISLISP provides several mechanisms for specifying how a new instance is to be initialized. For example, it is possible to specify the initial values for slots in newly created instances by providing default initial values. Further initialization activities can be performed by methods written for generic functions that are part of the initialization protocol.

## 11 Scope and extent

In describing ISLISP, the notions of **scope** and **extent** are useful. The first is a syntactic concept, the latter is a semantic concept. Although syntactic constructs, especially identifiers, are used to refer to runtime entities (i.e., objects arising during execution), a single entity cannot have both scope and extent. **Scope** is a feature of an identifier, referring to that textual part of an ISLISP
text (see §4.38 and §5) within which this identifier occurs with unique meaning. *Extent* refers to
the interval of execution time during which a certain object exists.

A *namespace* is a mapping from identifiers to meanings. In ISLISP there are six namespaces:
variable, dynamic variable, function, class, block, and tagbody tag. It is therefore possible for a
single identifier to have any or all of these six meanings, depending on the context. For example,
an identifier's meaning is determined by the function namespace when the identifier appears in
the operator position of a function application form, whereas the same identifier's meaning is
determined by the variable namespace if it appears in an argument position in the same form.

11.1 The lexical principle

ISLISP is designed following the principle of *lexical visibility*. This principle states that an
ISLISP text must be structured properly nested lexical blocks of visibility. Within a block, all
defined identifiers of that block and of all enclosing outer blocks are visible. Each identifier in a
namespace has the meaning determined by the innermost block that defines it.

ISLISP also supports a form of *dynamic binding*. Dynamic bindings are established and
accessed by a separate mechanism (i.e., *defdynamic, dynamic-let, and dynamic*). The dynamic
value associated with such an identifier is the one that was established by the most recently
executed *active block* that established it, where an *active* block is one that has been established
and not yet disestablished. Because a separate mechanism is used, the lexical meaning of and the
dynamic value associated with an identifier are simultaneously accessible wherever both are
declared.

11.2 Scope of identifiers

The *scope* of an identifier is that part of an ISLISP text where the meaning of the identifier is
defined. It starts textually with the definition point—a point that is specified individually for
each form that establishes an identifier. Only identifiers can have a scope.

For each namespace, if an identifier has scope $s_a$ and an identical identifier (in the same
namespace) has nested scope $s_b$, then the scope $s_b$ of the inner identifier and every scope
contained in it are not part of the scope $s_a$. It is said that the inner scope *shadows* the outer
scope.

Each complete ISLISP text unit is processed in a scope called the *top-level scope*.

In each namespace, nested binding forms shadow outer binding forms and defining forms.

11.3 Some specific scope rules

The top-level scope is the scope of identifiers of required built-in functions, special operators,
defining operators, and constants.

Reserved identifiers are not subject to the lexical principle, because they are not identifiers.
They cannot be defined or bound. See §8.
(let ((a1 f-a1)
  ...
  (x f-x)
  (z1 f-z1))
  ...
  ; now a1...x...z1 are applicable, their scope begins here
(let ((a2 f-a2)) ; a1...x...z1 might be defined newly, but:
  ...
  ; the outer a1...x...z1 are still usable
  (x f-x2) ; the inner a2...x...z2 are not yet usable
  ...
  (z2 f-z2)) ; the scope of the outer x becomes shadowed
  ; the scope for the inner a2...x...z2 starts
  ...
  ; now outer a1, z1 and inner a2...x...z2 are applicable
  )
  ; scopes of a2...x...z2 end here
  ...
  ; scope of outer x becomes unshadowed
  )
  ; scopes of a1...x...z1 end here

Figure 2. Scope Example

11.4 Extent

Complementary to scope which is a syntactic concepts, extent is a semantic concept: It
describes the lifetime of entities.

Objects are created at some time during execution. In most cases, it is undetermined when an
object ends its existence: its lifetime begins when the object is created and ends when reference
to it is no longer possible (and the object is subject to garbage collection). In this case the
object is said to have indefinite extent.

In other cases the processor creates entities that are associated with prepared text. The lifetime
of such objects begins at the activation point of a defining construct and ends at the end of
activation; in this case the object is said to have dynamic extent.

During execution, defining forms and the following binding forms create bindings at their
activation points:

block  let     with-open-io-file
dynamic-let  let*   with-open-output-file
flet    tagbody with-standard-input
for     with-error-output with-standard-output
labels    with-open-input-file

The bindings established by defining forms may have indefinite extent. Even in local binding
constructs, bindings might not vanish upon activation end of the prepared block—if one or more
function objects are created during execution of the prepared block that contain references to
those bindings, the bindings will have a lifetime equal to the longest lifetime of those function
objects.

Example:

(defun copy-cell (x) (cons (car x) (cdr x)))
The scope of the identifier \( x \) is the body alone—i.e., \((\text{cons} \ (\text{car} \ x) \ (\text{cdr} \ x))\). The meaning of \( x \) is defined for the entire body. \( x \), as identifier, cannot have an extent. The defun form for \texttt{copy-cell} is prepared for execution and thereby \texttt{copy-cell} becomes a prepared function. During execution the prepared function \texttt{copy-cell} might be activated. Activation in this case results in the creation of a binding between the variable denoted by \( x \) and the object which is used as argument. The binding of \( x \) is an entity whose extent lasts from the activation point to the activation end of the function. (In general the extent of a binding can last beyond the activation end, but this does not occur in this simple case.) We say that the binding of \( x \) is \textit{established} upon activation of the function and is \textit{disestablished} at activation end.

12 Forms and evaluation

12.1 Forms

Execution presupposes successful preparation for execution of an ISLISP text subject to the evaluation model. Execution is an activation of a prepared text form that results in a value and perhaps in some side effects.

An ISLISP text is a sequence of forms.

Throughout this document the value a form returns is described, but in general a form might not return if one of its subforms executes a \texttt{non-local exit} (see §14.7.1). Therefore, it should be understood that all such descriptions implicitly include the provision that \textit{if the form returns}, a particular value is returned.

The following are valid forms in ISLISP:

- Compound forms
  - Special forms
  - Defining forms
  - Function application forms
  - Macro forms
- Identifiers
- Literals

A form, when evaluated, returns an object as its value, though some forms may not return (e.g., \texttt{return-from}).

A compound form is written as \((\text{operator} \ \text{argument}^*)\). The \texttt{operator} must be a special operator, a defining operator, an identifier, or a lambda expression. The identifier names a function, a macro, or a generic function. It is a violation if \texttt{operator} is a literal.

A \texttt{toplevel form} is a form that is either not lexically nested within another form or is lexically nested only within one or more \texttt{progn} forms. Special forms and function application forms at toplevel are called \textit{set-up forms}. It is a violation if a defining form is not a toplevel form.
12.2 Function application forms

A function application form is a compound form whose operator is an identifier (naming a function) or whose operator is a lambda expression. All of the arguments are evaluated, from left to right, and the function is called with (or “applied to”) arguments that are, in the same order, the objects resulting from these evaluations. This document describes a function application form in the following format:

\[
\text{function-name argument*} \rightarrow \text{result-class}
\]

This describes an ordinary function.

\[
\text{generic-function-name argument*} \rightarrow \text{result-class}
\]

generic function

This describes a generic function.

\[
\text{local-function-name argument*} \rightarrow \text{result-class}
\]

local function

This describes an ordinary function that is available only in a specified lexical scope.

12.3 Special forms

A special form is a form whose arguments are treated in a special way; for example, arguments are not evaluated or are evaluated in a special order. It is implementation defined whether any special form is implemented as a macro (see §12.5 and §16). Special forms are recognized because they have a special operator in their operator position. The following are special operators:

- and
- assure
- block
- case
- case-using
- catch
- class
- cond
- convert
- dynamic
- dynamic-let
- let*
- let
- or
- prog
- function
- quote
- go
- return-from
- if
- set
- ignore-errors
- setf
- labels
- setq
- lambda
- tagbody
- the
- throw
- unwind-protect
- with-error-output
- with-handler
- with-open-input-file
- with-open-io-file
- with-open-output-file
- with-standard-input
- with-standard-output

There might be additional, implementation-defined special operators.

This document describes the evaluation of special forms in the following format:

\[
\text{special-operator argument*} \rightarrow \text{result-class}
\]

special operator
12.4 Defining forms

A defining form is a toplevel special form (see §12.3) that establishes a binding between name and an object which is the result of handling the arguments according to the semantics implied by defining-form-name; it is a violation if a defining form is not a toplevel form. For each namespace, defining forms can occur at most once for the same name and, in case of method definitions for the same parameter profile. A defining form is a compound form whose operator is a defining operator. These are the defining operators:

```
defclass  defdynamic  defglobal  defmethod
  defconstant  defgeneric  defmacro  defun
```

This document describes defining forms in the following format:

```
(defining-form-name name argument*)  →  <symbol>  defining operator
```

12.5 Macro forms

Macro forms are expanded during preparation for execution.

For information on how macros are processed, see §16.

12.6 The evaluation model

This section provides an operational model of the process of evaluation.

The process of evaluation has two steps: A valid ISLISP text is first prepared for execution, and then the prepared text is executed. Both the process of preparing the text for execution and the properties of a prepared text are implementation dependent, except that all macros have been expanded in the prepared text (see §16). The process of execution which follows is described in terms of fully macroexpanded forms.

A prepared form is executed as follows:

1. If the form is a literal, the result is the form itself.

2. If the form is an identifier, the result is the object denoted by the identifier in the variable namespace of the current lexical environment. An error shall be signaled if no binding has been established for the identifier in the variable namespace of current lexical environment (see §9.2) (error-id. unbound-variable).

3. If the form is a compound form, then one of the following cases must apply:

   (a) If the operator is a special operator, then the form is a special form and its arguments are evaluated according to the definition of the special operator. For example, if first evaluates its condition expression and, depending on the result obtained, it then evaluates the “then” form or the “else” form.
(b) If the operator names a defining form, then the first argument is an identifier. The remaining arguments are handled according to the specification of the defining form and the resulting object is used to establish a binding between the identifier and that object in the appropriate namespace.

(c) If the operator is a lambda-expression, then the arguments are evaluated. The order of evaluation of the arguments is sequentially from left to right. Then the function denoted by the lambda-expression is invoked with the evaluated arguments as actual parameters. The result is the value returned by the function, if it returns.

Example:

\[
((\text{lambda} \ (x) \ (+ \ x \ x)) \ 4) \Rightarrow 8
\]

(d) Otherwise, the compound form is a function application form. The operator position of the form is an identifier; it will be evaluated in the function namespace to produce a function to be called. An error shall be signaled if no binding has been established for the identifier in the function namespace of the current lexical environment (see §9.2) (error-id. undefined-function). The arguments are evaluated in order from left to right. Then the function is invoked with the evaluated arguments as actual parameters. The result is the value returned by the function, if it returns.

4. Otherwise, an error shall be signaled (error-id. undefined-function).

See §9.2 for descriptions of error situations that might occur during execution of the above cases.

12.7 Functions

A function can receive some objects as arguments upon activation. If a function returns, it returns an object as its value. A function binding can be established in one of the following ways:

- by using function defining forms; i.e., the defun, defgeneric, and defclass defining forms
- by using labels and flet special forms

---

(functionp obj) \rightarrow boolean

Returns t if obj is a (normal or generic) function; otherwise, returns nil. obj may be any ISLISP object.

Example:

\[
\text{(functionp (function car))} \Rightarrow t
\]

Function bindings are entities established during execution of a prepared labels or flet forms or by a function-defining form. A function binding is an association between an identifier, function-name, and a function object that is denoted by function-name—if in operator position—or by (function function-name) elsewhere.
(function function-name)  →  <function>  
#:function-name  →  <function>  
special operator  
syntax

This special form denotes a reference to the function named by function-name. This special form is used to refer to identifiers defined by function-defining forms, labels, or flet which are not in operator position.

(function function-name) can be written as #:function-name.

It returns the function object named by function-name.

An error shall be signaled if no binding has been established for the identifier in the function namespace of current lexical environment (see §9.2) (error-id. undefined-function). The consequences are undefined if the function-name names a macro or special form.

Example:

    (funcall (function -) 3)  ⇒  -3
    (apply #:'- '(4 3))       ⇒  1

(lambda lambda-list form*)  →  <function>  
special operator

Where:

\[
\textit{lambda-list} ::= (\textit{identifier}* \textit{[:rest identifier]} | \textit{identifier}* [:rest identifier])
\]

and where no \textit{identifier} may appear more than once in \textit{lambda-list}.

Execution of the \textit{lambda} special form creates a function object.

The scope of the identifiers of the \textit{lambda-list} is the sequence of forms form*, collectively referred to as the body.

When the prepared function is activated later (even if transported as object to some other activation) with some arguments, the body of the function is evaluated as if it was at the same textual position where the \textit{lambda} special form is located, but in a context where the lambda variables are bound in the variable namespace with the values of the corresponding arguments. A \textit{:rest} or \textit{:rest} variable, if any, is bound to the list of the values of the remaining arguments. An error shall be signaled if the number of arguments received is incompatible with the specified \textit{lambda-list} (error-id. \textit{arity-error}).

Once the lambda variables have been bound, the body is executed. If the body is empty, \textit{nil} is returned otherwise the result of the evaluation of the last form of body is returned if the body was not left by a non-local exit (see §14.7.1).

If the function receives a \textit{&rest} or \textit{:rest} parameter \textit{R}, the list \textit{L₁} to which that parameter is bound has indefinite extent. \textit{L₁} is newly allocated unless the function was called with \textit{apply} and

PUBLIC DOMAIN
\textbf{ISLISP Working Draft 22.0}

\(R\) corresponds to the final argument, \(L_2\), to that call to \texttt{apply} (or some subcall of \(L_2\)), in which case it is implementation defined whether \(L_1\) shares structure with \(L_2\).

\textbf{Example:}

\[
\begin{aligned}
&((\texttt{lambda} (x y) (* (* x x) (* y y))) 3 4) \\
&\Rightarrow 25 \\
&((\texttt{lambda} (x y \rest z) z) 3 4 5 6) \\
&\Rightarrow (5 6) \\
&((\texttt{lambda} (x y :rest z) z) 3 4 5 6) \\
&\Rightarrow (5 6) \\
&(\texttt{funcall} (\texttt{lambda} (x y) (- y (* x y))) 7 3) \\
&\Rightarrow -18
\end{aligned}
\]

\[
\begin{aligned}
&\texttt{(labels ((function-name lambda-list form*)* body-form*) } \rightarrow <\text{object}> \text{ special operator}\ \\
&\texttt{(flet ((function-name lambda-list form*)* body-form*) } \rightarrow <\text{object}> \text{ special operator}
\end{aligned}
\]

The \texttt{flet} and \texttt{labels} special forms allow the definition of new identifiers in the function namespace for function objects.

In a \texttt{labels} special form the scope of an identifier \texttt{function-name} is the whole \texttt{labels} special form (excluding nested scopes, if any); for the \texttt{flet} special form, the scope of an identifier is only the \texttt{body-form*}. Within these scopes, each \texttt{function-name} is bound to a function object whose behavior is equivalent to \texttt{(lambda lambda-list form*)}, where free identifier references are resolved as follows:

- For a \texttt{labels} form, such free references are resolved in the lexical environment that was active immediately outside the \texttt{labels} form augmented by the function bindings for the given \texttt{function-names} (i.e., any reference to a function \texttt{function-name} refers to a binding created by the \texttt{labels}).

- For a \texttt{flet} form, free identifier references in the \texttt{lambda-expression} are resolved in the lexical environment that was active immediately outside the \texttt{flet} form (i.e., any reference to a function \texttt{function-name} are not visible).

During activation, the prepared \texttt{labels} or \texttt{flet} establishes function bindings and then evaluates each \texttt{body-form} in the body sequentially; the value of the last one (or \texttt{nil} if there is none) is the value returned by the special form activation.

No \texttt{function-name} may appear more than once in the function bindings.

\textbf{Example:}

\[
\begin{aligned}
&\texttt{(labels ((evenp n)} \\
&\texttt{\quad (if (= n 0)} \\
&\texttt{\quad \quad t} \\
&\texttt{\quad \quad (oddp (- n 1)))}) \\
&\texttt{\quad (oddp n)} \\
&\texttt{\quad (if (= n 0)} \\
&\texttt{\quad \quad (oddp n) \quad \quad t)} \\
&\texttt{\quad \quad (nil))}
\end{aligned}
\]
nil
(evenp (- n 1)))

(evenp 88)) ⇒ t

(flet ((f (x) (+ x 3)))
  (flet ((f (x) (+ x (f x))))
    (f 7))) ⇒ 17

(apply function obj* list) → \textit{<object>}

Applies \textit{function} to the arguments, \textit{obj*}, followed by the elements of \textit{list}, if any. It returns the value returned by \textit{function}.

An error shall be signaled if \textit{function} is not a function (error-id. \textit{domain-error}). Each \textit{obj} may be any ISLISP object. An error shall be signaled if \textit{list} is not a proper list (see \textit{null}) (error-id. \textit{improper-argument-list}).

\textbf{Example:}

(apply (if (< 1 2) (function max) (function min))
  1 2 (list 3 4)) ⇒ 4

(defun compose (f g)
  (lambda (:rest args)
    (funcall f (apply g args)))))
  ⇒ compose

(funcall (compose (function \textit{sqrt}) (function *)) 12 75)
  ⇒ 30

(funcall function obj*) → \textit{<object>}

Activates the specified function \textit{function} and returns the value that the function returns. The \textit{i}th argument (2 ≤ \textit{i}) of \textit{funcall} becomes the \textit{(i - 1)}th argument of the function. \textit{funcall} could have been defined using \textit{apply} as follows:

(defun funcall (function :rest arguments)
  (apply function arguments))

An error shall be signaled if \textit{function} is not a function (error-id. \textit{domain-error}). Each \textit{obj} may be any ISLISP object.

\textbf{Example:}

(let ((x '(1 2 3)))
(funcall (cond ((listp x) (function car))
               (t (lambda (x) (cons x 1))) x))
⇒ 1

12.8 Defining operators

Although the names defined by defining forms can be used throughout the current toplevel scope, the prepared toplevel forms in an ISLISP text unit are executed sequentially from left to right.

Two defining forms with the same identifier in the same namespace are not allowed in one toplevel scope.

(defconstant name form) → <symbol> defining operator

This form is used to define a named constant in the variable namespace of the current toplevel scope. The scope of name is the entire current toplevel scope except the body form.

Although name is globally constant, a variable binding for name can be locally established by a binding form.

The result of the evaluation of form is bound to the variable named by name. The binding and the object created as the result of evaluating the second argument are immutable. The symbol named name is returned.

Example:

    (defconstant e 2.7182818284590451) ⇒ e
    e ⇒ 2.7182818284590451
    (defun f () e)
    (f) ⇒ 2.7182818284590451

(defglobal name form) → <symbol> defining operator

This form is used to define an identifier in the variable namespace of the current toplevel scope. The scope of name is the entire current toplevel scope except the body form.

form is evaluated to compute an initializing value for the variable named name. Therefore, defglobal is used only for defining variables and not for modifying them. The symbol named name is returned.

A lexical variable binding for name can still be locally established by a binding form; in that case, the local binding lexically shadows the outer binding of name defined by defglobal.

Example:
(defglobal today 'wednesday) ⇒ today
today ⇒ wednesday
(defun what-is-today () today) ⇒ what-is-today
(what-is-today) ⇒ wednesday
(let ((what-is-today 'thursday)) (what-is-today)) ⇒ wednesday
(let ((today 'thursday)) (what-is-today)) ⇒ wednesday

(defdynamic name form) → <symbol> defining operator

This form is used to define a dynamic variable identifier in the dynamic variable namespace. The scope of name is the entire current toplevel scope except the body form.

The symbol named name is returned.

Example:

(defdynamic *color* 'red) ⇒ *color*
(dynamic *color*) ⇒ red
(defun what-color () (dynamic *color*))
⇒ what-color
(what-color) ⇒ red
(dynamic-let ((*color* 'green)) (what-color))
⇒ green

(defun function-name lambda-list form*) → <symbol> defining operator

The defun-form defines function-name as an identifier in the function namespace, function-name is bound to a function object equivalent to (lambda lambda-list form*).

The scope of function-name is the whole current toplevel scope. Therefore, the definition of a function admits recursion, occurrences of function-name within the form* refer to the function being defined. The binding between function-name and the function object is immutable.

defun returns the function name which is the symbol named function-name. The free identifiers in the body form* (i.e., those which are not contained in the lambda list) follow the rules of lexical scoping.

Example:

(defun caar (x) (car (car x))) ⇒ caar
ISLISP Working Draft 22.0

13 Predicates

13.1 Boolean values

The values t and nil are called booleans. t denotes true, and nil is the only value denoting false. Predicates, also called boolean functions, are functions that return t when satisfied and nil otherwise.

Any object other than nil is treated as true (not just t). When objects are treated as true or nil this way they are called quasi-booleans.

t is an identifier naming the symbol t, and nil is an identifier naming the symbol nil (which is also the empty list). nil is the unique instance of the <null> class.

Like boolean functions, the and and or special forms return truth values; however, these truth values are nil when the test is not satisfied and a non-nil value otherwise. The result of and and or are quasi-booleans.

| t    | → <symbol>                      | named constant |
| nil  | → <null>                        | named constant |

t is a named constant whose value is the symbol t itself. nil is a named constant whose value is the symbol nil itself.

13.2 Class predicates

The following functions are one-argument class membership predicates:

| basic-array*-p | floatp   | integerp | stringp |
| basic-array-p  | functionp| listp    | symbolp |
| basic-vector-p | general-array*-p | null    |
| characterp     | general-vector-p | numberp |
| cons            | generic-function-p | streamp |

In addition, the function instancep is a two-argument predicate that tests membership in an arbitrary class.

13.3 Equality

| (eq obj1 obj2) → boolean | function |
| (eql obj1 obj2) → boolean | function |

eq and eql test whether obj1 and obj2 are same identical object. They return t if the objects are the same; otherwise, they return nil. Two objects are the same if there is no operation that could distinguish them (without modifying them), and if modifying one would modify the other the same way.
For eq, the consequences are implementation defined if both obj1 and obj2 are numbers or both are characters. For eql the meaning for numbers and characters is defined as follows:

- If obj1 and obj2 are numbers, eql tests whether they are direct instances of the same class and have the same value.

  If an implementation supports positive and negative zeros as distinct values, then (eql 0.0 -0.0) returns nil. When the syntax -0.0 is read and it is interpreted as the value 0.0 then (eql 0.0 -0.0) returns t.

- If obj1 and obj2 are characters, eql tests whether they are the same character (see char=).

**Example:**

```lisp
(eql () ()) ⇒ t
(eq () ()) ⇒ t
(eql '() '()) ⇒ t
(eq '() '()) ⇒ t
(eql 'a 'a) ⇒ t
(eq 'a 'a) ⇒ t
(eql 'a 'A) ⇒ t
(eq 'a 'A) ⇒ t
(eql 'a 'b) ⇒ nil
(eq 'a 'b) ⇒ nil
(eql 'f 'nil) ⇒ nil
(eq 'f 'nil) ⇒ nil
(eql 2 2) ⇒ t
(eq 2 2) ⇒ nil or t (implementation-defined)
(eql 2 2.0) ⇒ nil
(eq 2 2.0) ⇒ nil
(eql 100000000 100000000) ⇒ t
(eq 100000000 100000000) ⇒ nil or t (implementation-defined)
(eql 10.000000 10.0) ⇒ t
(eq 10.000000 10.0) ⇒ nil or t (implementation-defined)
(eql (cons 1 2) (cons 1 2)) ⇒ nil
(eq (cons 1 2) (cons 1 2)) ⇒ nil
(let ((x 'a)) (eq x x)) ⇒ t
(let ((x 'a)) (eql x x)) ⇒ t
(let ((a) 'a)) ⇒ nil or t (implementation-defined)
(let ((a) 'a)) ⇒ nil or t (implementation-defined)
(let ((x 'b))
  (y '(a b)))
(eql x (cdr y)) ⇒ nil or t (implementation-defined)
(let ((x 'b))
  (y '(a b)))
(eq x (cdr y)) ⇒ nil or t (implementation-defined)
(eql 'b (cdr '(a b))) ⇒ nil or t (implementation-defined)
(eq 'b (cdr '(a b))) ⇒ nil or t (implementation-defined)
(let ((p (lambda (x) x)))
  (eql p p)) ⇒ t
(let ((p (lambda (x) x)))
  (eq p p)) ⇒ t
(let ((x "a")) (eql x x)) ⇒ t
```
(let ((x "a")) (eq x x)) ⇒ t
(eq1 "a" "a") ⇒ nil or t (implementation-defined)
(eq1 "a" "a") ⇒ nil or t (implementation-defined)
(let ((x "")) (eq x x)) ⇒ t
(let ((x "")) (eq x x)) ⇒ t
(eq1 "" "") ⇒ nil or t (implementation-defined)
(eq1 "" "") ⇒ nil or t (implementation-defined)
(eq1 \\a \\A) ⇒ nil
(eq1 \\a \\A) ⇒ nil
(eq1 \\a \\a) ⇒ t
(eq1 \\a \\a) ⇒ nil or t (implementation-defined)
(eq1 \\space \\space) ⇒ t
(eq1 \\space \\space) ⇒ nil or t (implementation-defined)
(eq1 \\space \\space) ⇒ t
(eq1 \\space \\space) ⇒ nil or t (implementation-defined)

(equal obj1 obj2) → boolean

function

This function tests whether obj1 and obj2 are isomorphic—i.e., whether obj1 and obj2 denote the same structure with equivalent values. equal returns t if the test was satisfied, and nil if not. Specifically:

If obj1 and obj2 are direct instances of the same class, equal returns t if they are eq. Otherwise (if they are direct instances of the same class but not eq), the result is t if one of the following cases applies:

(a) lists: either obj1 and obj2 are both the empty list (i.e., nil), or

(and (equal (car obj1) (car obj2))
     (equal (cdr obj1) (cdr obj2))) holds;

(b) basic arrays:

(equal (array-dimensions obj1)
       (array-dimensions obj2))

holds and for every valid reference (aref obj1 \ind1 \ldots \indn)

(equal (aref obj1 \ind1 \ldots \indn)
       (aref obj2 \ind1 \ldots \indn)) is satisfied.

Otherwise the value is nil.

obj1 and obj2 may be any ISLISP objects.

Example:

(equal 'a 'a) ⇒ t
(equal 2 2) ⇒ t
(equal 2 2.0) ⇒ nil
13.4 Logical connectives

\[(\text{not } \text{obj}) \rightarrow \text{boolean} \quad \text{function}\]

This predicate is the logical “not” (or “\(\neg\)”). It returns \(t\) if \(\text{obj}\) is \(\text{nil}\) and \(\text{nil}\) otherwise. \(\text{obj}\) may be any ISLISP object.

**Example:**

\[
\begin{align*}
\text{(not} \ t) & \Rightarrow \text{nil} \\
\text{(not } \text{()}) & \Rightarrow \text{t} \\
\text{(not } \text{'nil}) & \Rightarrow \text{t} \\
\text{(not} \text{ nil}) & \Rightarrow \text{t} \\
\text{(not} \text{ 3}) & \Rightarrow \text{nil} \\
\text{(not} \text{ (list))} & \Rightarrow \text{t} \\
\text{(not} \text{ (list} 3)) & \Rightarrow \text{nil}
\end{align*}
\]

\[(\text{and } \text{form}^*) \rightarrow \text{<object>} \quad \text{special operator}\]

and is the sequential logical “and” (or “\(\land\)”). \(\text{forms}\) are evaluated from left to right until either one of them evaluates to \(\text{nil}\) or else none are left. If one of them evaluates to \(\text{nil}\), then \(\text{nil}\) is returned from the \(\text{and}\); otherwise, the value of the last evaluated form is returned. The form \(\text{and}\) is equivalent to the following:

\[
\begin{align*}
\text{(and)} & \equiv \; \text{'}t \\
\text{(and } \text{form}) & \equiv \; \text{form} \\
\text{(and } \text{form}_1 \; \text{form}_2 \; \ldots \; \text{form}_n) & \equiv \; (\text{if } \text{form}_1 \; \text{(and } \text{form}_2 \; \ldots \; \text{form}_n) \; \text{'nil})^2
\end{align*}
\]

**Example:**

\(^2\)For the definition of \(\text{if}\), see §14.4 below.
ISLISP Working Draft 22.0

(and (= 2 2) (> 2 1))  ⇒ t
(and (= 2 2) (< 2 1))  ⇒ nil
(and (eql 'a 'a) (not (> 1 2)))  ⇒ t
(let ((x 'a)) (and x (setq x 'b)))  ⇒ b
(let ((x nil)) (and x (setq x 'b)))  ⇒ nil
(let ((time 10))
  (if (and (< time 24) (> time 12))
      (- time 12) time))  ⇒ 10
(let ((time 18))
  (if (and (< time 24) (> time 12))
      (- time 12) time))  ⇒ 6

(or form*) → <object>  

or is the sequential logical “or” (or “V”). forms are evaluated from left to right until either one of them evaluates to a non-nil value or else none are left. If one of them evaluates to a non-nil value, then this non-nil value is returned, otherwise nil is returned. The form or is equivalent to the following:

(or)  == 'nil
(or form)  == form
(or form1 form2 ... formn)  == ((lambda (var)
    (if var (or form2 ... formn)) form1)
where var does not occur in form2 ... formn

Example:

(or (= 2 2) (> 2 1))  ⇒ t
(or (= 2 2) (< 2 1))  ⇒ t
(let ((x 'a)) (or x (setq x 'b)))  ⇒ a
(let ((x nil)) (or x (setq x 'b)))  ⇒ b

14 Control structure

14.1 Constants

constant → <object>  

There are three kinds of constants: literals, quoted expressions, and named constants. Quoted expressions are described below.

The consequences are undefined if an attempt is made to alter the value of a constant.

PUBLIC DOMAIN
The result of evaluating the literal constant constant is constant itself. Instances of the following classes are literal constants: <basic-array>, <character>, and <number>

Example:

\[
\begin{align*}
\text{#2A(a b c (d e f))} & \Rightarrow \text{#2A(a b c (d e f))} \\
\text{\#\textbackslash a} & \Rightarrow \text{\#\textbackslash a} \\
145932 & \Rightarrow 145932 \\
\text{"abc"} & \Rightarrow \text{"abc"} \\
\text{#(a b c)} & \Rightarrow \text{#(a b c)}
\end{align*}
\]

<table>
<thead>
<tr>
<th>special operator</th>
<th>syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>(quote obj) \rightarrow &lt;object&gt;</td>
<td></td>
</tr>
<tr>
<td>'obj \rightarrow &lt;object&gt;</td>
<td></td>
</tr>
</tbody>
</table>

A quoted expression denotes a reference to an object. This notation is used to include any object in an ISLISP text.

The character ' (apostrophe or single quote) is syntax for quotation. That is, (quote a) \equiv 'a.

The result of the evaluation of the quote special form is obj.

Example:

\[
\begin{align*}
\text{(quote a)} & \Rightarrow a \\
\text{(quote #(a b c))} & \Rightarrow #(a b c) \\
\text{(quote (+ 1 2))} & \Rightarrow (+ 1 2) \\
\text{'(())} & \Rightarrow \text{nil} \\
\text{'a} & \Rightarrow a \\
\text{'#(a b c)} & \Rightarrow #(a b c) \\
\text{'(car 1)} & \Rightarrow \text{(car 1)} \\
\text{'(+ 1 2)} & \Rightarrow (+ 1 2) \\
\text{'(quote a)} & \Rightarrow \text{(quote a)} \\
\text{''a} & \Rightarrow \text{quote}
\end{align*}
\]

The consequences are undefined if an attempt is made to alter the value of a quoted expression.

14.2 Variables

Variable bindings are entities established during execution of the prepared variable-binding forms or by the activation of functions.

A variable is used to refer to an association between an identifier and an ISLISP object, and is denoted by that identifier. The association can be altered (by assignment) using the \texttt{setf} special form or \texttt{setq} special form.

The following are variable binding forms:

PUBLIC DOMAIN
defglobal  let  for  let

\[ \text{var} \rightarrow \langle \text{object} \rangle \]

The value of \( \text{var} \) is the object associated with \( \text{var} \) in its variable binding.

**Example:**

\[
\begin{align*}
\text{(defglobal x 0)} & \quad \Rightarrow x \\
x & \quad \Rightarrow 0 \\
\text{(let ((x 1)) x)} & \quad \Rightarrow 1 \\
x & \quad \Rightarrow 0
\end{align*}
\]

\[ \text{(setq var form)} \rightarrow \langle \text{object} \rangle \]

This form represents an assignment to the variable denoted by the identifier. In consequence, the identifier may designate a different object than before, the value of \( \text{form} \).

The result of the evaluation of \( \text{form} \) is returned. This result is used to modify the variable binding denoted by the identifier \( \text{var} \) (if it is mutable). \text{setq} can be used only for modifying bindings, and not for establishing a variable. The \text{setq} special form must be contained in the scope of \( \text{var} \), established by \text{defglobal}, \text{let}, \text{let*}, \text{for}, or a lambda expression.

**Example:**

\[
\begin{align*}
\text{(defglobal x 2)} & \quad \Rightarrow x \\
(+ x 1) & \quad \Rightarrow 3 \\
\text{(setq x 4)} & \quad \Rightarrow 4 \\
(+ x 1) & \quad \Rightarrow 5 \\
\text{(let ((x 1)) (setq x 2) x)} & \quad \Rightarrow 2 \\
(+ x 1) & \quad \Rightarrow 5
\end{align*}
\]

\[ \text{(setf place form)} \rightarrow \langle \text{object} \rangle \]

This macro is used for generalized assignment.

\text{setf} takes a \( \text{place} \) and stores in this place the result of the evaluation of the form \( \text{form} \). The \( \text{place} \) form is not evaluated as a whole entity, but subforms of \( \text{place} \) are evaluated sequentially from left to right to determine a place to be assigned a value. When \( \text{place} \) is denoted by an identifier, \text{setf} behaves exactly as \text{setq}. The returned value is the result of the evaluation of \( \text{form} \). The valid places for the \text{setf} special form are as follows:
variables

(dynamic bindings (dynamic \textit{var})

the components of a basic-array (aref basic-array \textit{z}_1 \ldots \textit{z}_n)

the components of a general array (garef general-array \textit{z}_1 \ldots \textit{z}_n)

the components of a list (elt list \textit{z})

the components of a vector (elt basic-vector \textit{z})

the left component of a cons (car cons)

the right component of a cons (cdr cons)

a property of a symbol (property symbol property)

a slot of an instance of a class (reader-function-name \textit{instance})

A place can also be a macro form that expands (during preparation for execution) into a place or a function application form with operator \textit{op} for which \textit{setf} is defined or for which a generic function named (setf \textit{op}) has been defined. In these last two cases, that function will receive as arguments the new value to be assigned followed by the objects that resulted from evaluating the arguments of the function application form.

Example:

\begin{verbatim}
(setf (car x) 2) ⇒ 2
In the cons \textit{x}, the car now is 2.

(defmacro first (spot)
  '(car ,spot)) ⇒ first
(setf (first x) 2) ⇒ 2
In the cons \textit{x}, the car now is 2.
\end{verbatim}

\begin{verbatim}
(let ((\textit{var} \textit{form})*) \textit{body-form}*) → <object> special operator
\end{verbatim}

The \texttt{let} special form is used to define a scope for a group of identifiers for a sequence of forms \textit{body-form}*(collectively referred to as the \textit{body}). The list of pairs (\textit{var} \textit{form})* is called the \texttt{let} variable list. The scope of the identifier \textit{var} is the \textit{body}.

The \textit{forms} are evaluated sequentially from left to right; then each variable denoted by the identifier \textit{var} is initialized to the corresponding value. Using these bindings along with the already existing bindings of visible identifiers the \textit{body-forms} are evaluated. The returned value of \texttt{let} is the result of the evaluation of the last \textit{body-form} of its body (or \texttt{nil} if there is none).

No \textit{var} may appear more than once in \texttt{let} variable list.

\textbf{Note}: Although this form is a special form, one can think of it as a macro whose rewriting rules are as follows:

\begin{verbatim}
(let () \textit{body-form}*) ≡ (progn \textit{body-form}*)
(let ((\textit{var}_1 \textit{form}_1) (\textit{var}_2 \textit{form}_2) ... (\textit{var}_n \textit{form}_n)) \textit{body-form}*)
\end{verbatim}
Example:

\[
\begin{align*}
\text{let} & \ (x \ 2 \ y \ 3) \\
(* & \ x \ y) \quad \Rightarrow \ 6 \\
\text{let} & \ (x \ 2 \ y \ 3) \\
(\text{let} & \ (x \ 7) \\
(z & \ (+ \ x \ y))) \\
(* & \ z \ x)) \quad \Rightarrow \ 35 \\
\text{let} & \ (x \ 1 \ y \ 2) \\
(\text{let} & \ ((x \ y) \ (y \ x)) \\
\text{list} & \ x \ y)) \quad \Rightarrow \ (2 \ 1)
\end{align*}
\]

\[
\text{let}\ast \ ((\text{var} \ \text{form}\ast) \ \text{body-form}\ast) \Rightarrow \text{<object>} \quad \text{special operator}
\]

The \text{let}\ast \text{form} is used to define a scope for a group of identifiers for a sequence of forms \text{body-form}\ast (collectively referred to as the \text{body}). The first subform (the \text{let}\ast variable list) is a list of pairs \text{var form}. The scope of an identifier \text{var} is the \text{body} along with all \text{form} forms following the pair \text{var form} in the \text{let}\ast variable list.

For each pair \text{var form} the following is done: \text{form} is evaluated in the context of the bindings in effect at that point in the evaluation. The result of the evaluation is bound to its associated variable named by the identifier \text{var}. These variable bindings enlarge the set of current valid identifiers perhaps shadowing previous variable bindings (in case some \text{var} was defined outside), and in this enlarged or modified environment the \text{body-forms} are executed. The returned value of \text{let}\ast is the result of the evaluation of the last form of its body (or \text{nil} if there is none).

\textbf{Note:} Although this form is a special form, one can think of it as a macro whose rewriting rules are as follows:

\[
\begin{align*}
\text{let}\ast & \ (\text{body-form}\ast) \equiv \ \text{progn} \ \text{body-form}\ast \\
(\text{let} & \ ((\text{var} \ \text{form}_1) \ \text{body-form}\ast)) \\
(\text{var} \ \text{form}_2) & \ \text{let} ((\text{var} \ \text{form}_2) \ \text{body-form}\ast) \\
\ldots & \ \ldots \ \\
(\text{var} \ \text{form}_n) & \ \text{let} ((\text{var} \ \text{form}_n) \ \text{body-form}\ast) \ldots)
\end{align*}
\]

Example:

\[
\begin{align*}
\text{let} & \ (x \ 2 \ y \ 3) \\
(\text{let} & \ ((x \ 7) \\
(z & \ (+ \ x \ y))) \\
(* & \ z \ x)) \quad \Rightarrow \ 70
\end{align*}
\]

\footnote{For the definition of \text{progn} see §14.5 below.}

\footnote{For the definition of \text{lambda} see §12.7.}

PUBLIC DOMAIN
(let ((x 1) (y 2))
  (let* ((x y) (y x))
    (list x y)))  \Rightarrow  (2 2)

14.3 Dynamic variables

A dynamic variable is an association between an identifier \texttt{var} and an ISLISP object in the dynamic variable namespace. Dynamic variables implement a form of dynamic binding.

Dynamic variables are defined globally by \texttt{defdynamic} and are established during the execution of a prepared \texttt{dynamic-let}.

Dynamic variable bindings defined by \texttt{defdynamic} persist indefinitely whereas those established by \texttt{dynamic-let} are disestablished upon end of execution of this special form.

The value of a dynamic variable can be accessed by \texttt{(dynamic var)}.

\[(\texttt{dynamic \ \texttt{var}})  \rightarrow  \texttt{<object>}\] special operator

This special form denotes a reference to the identifier denoting a dynamic variable. This special form is not allowed in the scope of a definition of \texttt{var} which is not done by \texttt{defdynamic} or \texttt{dynamic-let}.

During activation, the current dynamic binding of the variable \texttt{var} is returned that was established most recently and is still in effect. An error shall be signaled if such a binding does not exist (error-id. \texttt{unbound-variable}).

\[(\texttt{setf (dynamic \ \texttt{var}}) \ \texttt{form})  \rightarrow  \texttt{<object>}\] special form

\[(\texttt{set-dynamic \ \texttt{form \ \texttt{var}}})  \rightarrow  \texttt{<object>}\] special operator

This special form denotes an assignment to a dynamic variable. This form can appear anywhere that \texttt{(dynamic \ \texttt{var})} can appear.

\texttt{form} is evaluated and the result of the evaluation is used to change the dynamic binding of \texttt{var}. An error shall be signaled if \texttt{var} has no dynamic value (error-id. \texttt{unbound-variable}). \texttt{setf} of dynamic can be used only for modifying bindings, and not for establishing them.

\[(\texttt{dynamic-let} \ ((\texttt{var \ form)*} \ \texttt{body-form)*})  \rightarrow  \texttt{<object>}\] special operator

The \texttt{dynamic-let} special form is used to establish dynamic variable bindings. The first subform (the \texttt{dynamic-let} variable list) is a list of pairs (\texttt{var form}). The scope of an identifier \texttt{var} defined by \texttt{dynamic-let} is the current toplevel scope. The extent of the bindings of each \texttt{var} is the extent of the body of the \texttt{dynamic-let}. The \texttt{dynamic-let} special form establishes dynamic variables for all \texttt{vars}.

References to a dynamic variable named by \texttt{var} must be made through the \texttt{dynamic} special form.

\textbf{PUBLIC DOMAIN} 37
All the initializing forms are evaluated sequentially from left to right, and then the values are associated with the corresponding vars. Using these additional dynamic bindings and the already existing bindings of visible identifiers, the forms body-form* are evaluated in sequential order. The returned value of dynamic-let is that of the last body-form of the body (or nil if there is none). The bindings are undone when control leaves the prepared dynamic-let special form.

Example:

```lisp
(defun foo (x)
  (dynamic-let ((y x))
    (bar 1))
⇒ foo

(defun bar (x)
  (+ x (dynamic y)))
⇒ bar

(foo 2)
⇒ 3
```

### 14.4 Conditional expressions

\[
\text{if test-form then-form [else-form]} \rightarrow <\text{object}>
\]

special operator

The `test-form` is evaluated. If its result is anything non-nil, the `then-form` is evaluated and its value is returned; otherwise (if the `test-form` returned `nil`), the `else-form` is evaluated and its value is returned.

If no `else-form` is provided, it defaults to `nil`.

Example:

```lisp
(if (> 3 2) 'yes 'no)  ⇒ yes
(if (> 2 3) 'yes 'no)  ⇒ no
(if (> 2 3) 'yes)     ⇒ nil
(if (> 3 2) (– 3 2) (+ 3 2)) ⇒ 1

(let ((x 7))
  (if (< x 0) x (– x)))  ⇒ -7
```

\[
\text{(cond test form*)} \rightarrow <\text{object}>
\]

special operator

Executing the prepared cond, the clauses `(test form*)` are scanned sequentially and in each case the `test` is evaluated; when `test` delivers a non-nil value the scanning process stops and all forms associated with the corresponding clause are sequentially evaluated and the value of the last one is returned. If no `test` is true, then nil is returned. If no `form` exists for the successful `test` then the value of this `test` is returned.
cond obeys the following equivalences:

\[
\begin{align*}
\text{(cond)} & \equiv \text{nil} \\
\text{(cond } t_1) & \equiv (\text{or } t_1 \\
& \quad (t_2 \ \text{form}_2 ) \\
& \quad \quad \quad \vdots \\
\text{(cond } t_1 \ \text{form}_1 ^+) & \equiv (\text{if } t_1 \\
& \quad (t_2 \ \text{form}_2 ) \\
& \quad \quad \quad \vdots \\
\end{align*}
\]

Example:

\[
\begin{align*}
\text{(cond } (> 3 \text{2} \text{'greater}) \\
& \quad (< 3 \text{2} \text{'less})) & \Rightarrow \text{greater} \\
\text{(cond } (> 3 \text{3} \text{'greater}) \\
& \quad (< 3 \text{3} \text{'less})) & \Rightarrow \text{nil} \\
\text{(cond } (> 3 \text{3} \text{'greater}) \\
& \quad (< 3 \text{3} \text{'less}) \\
& \quad (t \text{'equal})) & \Rightarrow \text{equal}
\end{align*}
\]

\[\begin{align*}
\text{(case } \text{keyform } ((\text{key}^+ \text{form}^+)^* [\text{t form}^+]) & \rightarrow \langle \text{object} \rangle & \text{special operator} \\
\text{(case-using } \text{predform } \text{keyform } ((\text{key}^+ \text{form}^+)^* [\text{t form}^+]) & \rightarrow \langle \text{object} \rangle & \text{special operator}
\end{align*}\]

The case and case-using special forms, called case forms, provide a mechanism to execute a matching clause from a series of clauses based on the value of a dispatching form keyform.

The clause to be executed is identified by a set of keys. A key can be any object. If the keylist of the last clause is t the associated clause is executed if no key matches the keyform.

keyform is a form to be computed at the beginning of execution of the case form. If the result of evaluating keyform is equivalent to a key, then the forms, if any, in the corresponding clause are evaluated sequentially and the value of the last one is returned as value of the whole case form.

case determines match equivalence by using eq; case-using match determines equivalence by using the result of evaluating predform. predform must be a boolean or quasi-boolean function that accepts two arguments, the value returned by keyform and key. If no form exists for a matching key, the case form evaluates to nil. If the value of keyform is different from every key, and there is a default clause, its forms, if any, are evaluated sequentially, and the value of the last one is the result of the case form.

The same key (as determined by the match predicate) may occur only once in a case form.

Example:

\[
\begin{align*}
\text{(case } (* 2 \text{3}) \\
& \quad ((2 \text{3 5 7} \text{'prime})
\end{align*}
\]
14.5 Sequencing forms

(progn form*) \rightarrow <object>  special operator

This special form allows a series of forms to be evaluated, where normally only one could be used.

The result of evaluation of the last form of form* is returned. All the forms are evaluated from left to right. The values of all the forms but the last are discarded, so they are executed only for their side effects. progn without forms returns nil.

Example:

(defglobal x 0) \Rightarrow x

(progn
  (setq x 5)
  (+ x 1)) \Rightarrow 6

(progn
  (format (standard-output) "4 plus 1 equals ")
  (format (standard-output) "D" (+ 4 1)))
\Rightarrow nil
prints 4 plus 1 equals 5

14.6 Iteration

\[(\text{while test-form body-form\*}) \rightarrow \text{<null>}\quad \text{special operator}\]

Iterates while the \text{test-form} returns a true value. Specifically:

1. \text{test-form} is evaluated, producing a value \(V_i\).
2. If \(V_i\) is \text{nil}, then the while form immediately returns \text{nil}.
3. Otherwise, if \(V_i\) is non-nil, the forms \text{body-form\*} are evaluated sequentially (from left to right).
4. Upon successful completion of the \text{body-forms\*}, the while form begins again with step 1.

Example:

\[
(\text{let ((x '()) (i 5))}
  (\text{while (> i 0) (setq x (cons i x)) (setq i (- i 1)))})
\]

\[
\Rightarrow (1 2 3 4 5)
\]

\[(\text{for (iteration-spec\*} (end-test result\*}) form\*) \rightarrow \text{<object>}\quad \text{special operator}\]

Where:

\[\text{iteration-spec} \quad ::= \quad (\text{var init [step]})\]

\text{for} repeatedly executes a sequence of forms \text{form\*}, called its \text{body}. It specifies a set of identifiers naming variables that will be local to the \text{for} form, their initialization, and their update for each iteration. When a termination condition is met, the iteration exits with a specified result value.

The scope of an identifier \text{var} is the \text{body}, the \text{steps}, the \text{end-test}, and the \text{result\*}. A \text{step} might be omitted, in which case the effect is the same as if (\text{var init var}) had been written instead of (\text{var init}). It is a violation if more than one \text{iteration-spec names the same var in the same for form}.

The \text{for} special form is executed as follows: The \text{init} forms are evaluated sequentially from left to right. Then each value is used as the initial value of the variable denoted by the corresponding identifier \text{var}, and the iteration phase begins.

Each iteration begins by evaluating \text{end-test}. If the result is \text{nil}, the forms in the \text{body} are evaluated sequentially (for side effects). Afterwards, the \text{step-forms} are evaluated sequentially.

PUBLIC DOMAIN
order from left to right. Then their values are assigned to the corresponding variables and the next iteration begins. If `end-test` returns a non-nil value, then the `result*` are evaluated sequentially and the value of the last one is returned as value of the whole `for` macro. If no `result` is present, then the value of the `for` macro is nil.

Example:

```lisp
(for ((vec (vector 0 0 0 0 0))
      (i 0 (+ i 1)))
  (= i 5) vec)
(setf (elt vec i)) ⇒ #(0 1 2 3 4)

(let ((x '(1 3 5 7 9)))
  (for ((x x (cdr x))
        (sum 0 (+ sum (car x))))
       ((null x) sum))) ⇒ 25
```

### 14.7 Non-local exits

#### 14.7.1 Establishing and invoking non-local exits

ISLISP defines three ways in which to perform non-local exits:

<table>
<thead>
<tr>
<th>Destination Kind</th>
<th>Established by</th>
<th>Invoked by</th>
<th>Operation Performed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>block name</code></td>
<td><code>block</code></td>
<td><code>return-from</code></td>
<td>lexical exit</td>
</tr>
<tr>
<td><code>tagbody tag</code></td>
<td><code>tagbody</code></td>
<td><code>go</code></td>
<td>lexical transfer of control</td>
</tr>
<tr>
<td><code>catch tag</code></td>
<td><code>catch</code></td>
<td><code>throw</code></td>
<td>dynamic exit</td>
</tr>
</tbody>
</table>

A **non-local exit** is an operation that forces transfer of control and possibly data from an invoking special form to a previously established point in a program, called the **destination** of the exit.

A **lexical exit** is a non-local exit from a `return-from` form to a `block` form which contains it both lexically and dynamically, forcing the `block` to return an object specified in the `return-from` form.

A **dynamic exit** is a non-local exit from a `throw` form to a `catch` form which contains it dynamically (but not necessarily lexically), forcing the `catch` to return an object specified in the `throw` form.

A **lexical transfer of control** is a non-local exit from a `go` form to a tagged point in a `tagbody` form which contains it both lexically and dynamically.

When a **non-local exit** is initiated, any potential destination that was established more recently than the destination to which control is being transferred is immediately considered invalid.

```
(block name form*) ⇒ <object>  special operator
(return-from name result-form) transfers control and data special operator
```
The block special form executes each form sequentially from left to right. If the last form exits normally, whatever it returns is returned by the block form.

The name in a block form is not evaluated; it must be an identifier. The scope of name is the body form*—only a return-from textually contained in some form can exit the block. The extent of name is dynamic.

If a return-from is executed, the result-form is evaluated. If this evaluation returns normally, the value it returns is immediately returned from the innermost lexically enclosing block form with the same name.

return-from is used to return from a block. name is not evaluated and must be an identifier. A block special form must lexically enclose the occurrence of return-from; the value produced by result-form is immediately returned from the block. The return-from form never returns and does not have a value.

An error shall be signaled if an attempt is made to exit a block after it has been exited (error-id. control-error); It is a violation if name is not an identifier. It is a violation if a block with a corresponding name does not exist. See §14.7.2 for other errors.

Example:

(block x
  (+ 10 (return-from x 6) 22)) ;; Bad programming style
⇒ 6

(defun f1 ()
  (block b
    (let ((f (lambda () (return-from b 'exit))))
      ... ; big computation
      (f2 f))))
⇒ f1

(defun f2 (g)
  ... ; big computation
  (funcall g))
⇒ f2

(f1)
⇒ exit

(block sum-block
  (for ((x '(1 a 2 3) (cdr x))
      (sum 0 (+ sum (car x)))))
  ((null x) sum)
  (cond ((not (numberp (car x))) (return-from sum-block 0))))
⇒ 0

(defun bar (x y)
  (let ((foo #\'car))
    (let ((result
      (block bl
        (setq foo (lambda () (return-from bl 'first-exit)))
        (if x (return-from bl 'second-exit) 'third-exit)))
      (if y (funcall foo nil)
          result)))
⇒ bar

[43]
The special forms `catch` and `throw` provide a facility for programming of structured non-local dynamic exits. A catch form and a throw form are said to correspond if the `tag-form` of the catch and the `tag-form` of the throw evaluate to the same object, a `catch tag`. A catch tag may be any object other than a number or a character; the comparison of `catch tags` uses `eq`.

The catch special form first evaluates the `tag-form` to produce a `catch tag`, and then executes each `form` sequentially from left to right. If execution of the `forms` finishes normally, whatever is returned by the last `form` is returned by the catch form.

Prior to execution of the `forms` of a catch form $C_0$, an association between the `catch tag` $T_0$ and the executing form $C_0$ is dynamically established, upon exit from $C_0$, the association is disestablished. If there was an outer association for the same `catch tag` $T_0$, it is hidden during the execution of $C_0$’s `forms`; only the most recently established (i.e., innermost) association for $T_0$ is ever visible.

If a `throw` special form is executed, it evaluates the `tag-form` producing a `catch tag` $T_1$, and then evaluates the `result-form` producing a result $R_1$. If there is a corresponding association between $T_1$ and some catch form $C_1$ that is executing, $R_1$ is immediately returned as the value of $C_1$. The `throw` form can be anywhere in the entire current toplevel scope; it need not be lexically contained within $C_1$.

An error shall be signaled if there is no outstanding catcher for a $T_1$ (`error-id. control-error`). See §14.7.2 for other errors.

Example:

```lisp
(defun foo (x)
  (catch 'block-sum (bar x)) => foo

(defun bar (x)
  (for ((1 x (cdr 1)))
    (sum 0 (+ sum (car 1))))
  (null 1) sum)
  (cond ((not (numberp (car 1))) (throw 'block-sum 0)))
  => bar

(foo '(1 2 3 4)) => 10
(foo '(1 2 a 4)) => 0
```
(tagbody \(\text{tagbody-tag} \mid \text{form}*\)) → <object>

(tagbody \text{tagbody-tag}) transfers control

\text{tagbody} executes the \text{forms} sequentially from left to right, discarding their values. If the execution of the last \text{form} completes normally, \text{nil} is returned by the \text{tagbody} special form.

The series of \text{tagbody-tags} and \text{forms} is collectively referred to as the body of a \text{tagbody} form.

An identifier \text{tagbody-tag} that appears at toplevel of the body denotes a \text{tagbody tag} that can be used with \text{go} to transfer control to that point in the body. Any compound form that appears is taken as a \text{form}. Literals are not permitted at the toplevel of a \text{tagbody}. No \text{tagbody-tag} may appear more than once in the tags in the body.

The namespace used for \text{tagbody} tags is distinct from that used for block tags.

At any point lexically contained in the \text{tagbody} a \text{form} (\text{go \ tag}) can be used to transfer control to a tag \text{tag} that appears among the \text{tagbody-tags}, except where a \text{tag} is shadowed according to the \text{lexical principle} (see §11.1).

A \text{tagbody-tag} established by \text{tagbody} has lexical scope, but the point in the program to which it refers has dynamic extent. Once \text{tagbody} has been exited, it is no longer valid to use \text{go} to transfer to any tag in its body.

The determination of which elements of the body are \text{tagbody-tags} and which are \text{forms} is made prior to any macro expansion of that element. If \text{form} is a macro form and its macro expansion is a symbol or literal, that atom is treated as a \text{form}, not as a \text{tagbody-tag}.

It is a violation if a \text{tagbody} tag is other than an identifier. See §14.7.2 for other errors.

\textbf{Note:} As a stylistic matter, programmers are not encouraged to use \text{tagbody} and \text{go} in everyday programming. The primary uses for which these forms are intended are for implementing other control abstractions (using macros), and for the occasional real-world situation that uses unstructured imperative transfer of control (such as a finite state machine).

\textbf{Example:}

\begin{verbatim}
(defmacro with-retry (\text{:rest forms})
  (let ((\text{tag} (gensym)))
    `(block ,\text{tag}
        (tagbody
         ,\text{tag}
         (return-from ,\text{tag}
            (flet ((\text{retry} () (go ,\text{tag})))
               ,\text{forms}))))))
  \Rightarrow \text{with-retry}

  (let ((\text{i -5}))
    (with-retry
      ;; if-error is a hypothetical error correction function
      ;; not supplied by ISLISP.
      (if-error (sqrt (setq \text{i} (+ \text{i} 4)))
        (\text{retry}))))
  \Rightarrow 1.7320508075688772
\end{verbatim}
14.7.2 Assuring data consistency during non-local exits

(unwind-protect form cleanup-form∗) → <object>  special operator

unwind-protect first evaluates form. Evaluation of the cleanup-forms always occurs, regardless of whether the exit is normal or non-local.

If the form exits normally yielding a value R, then if all of the cleanup-forms exit normally the value R is returned by the unwind-protect form.

If a non-local exit from form occurs, then the cleanup-forms are executed as part of that exit, and then if all of the cleanup-forms exit normally the original non-local exit continues.

The cleanup-forms are evaluated from left to right, discarding the resulting values. If execution of the cleanup-forms finishes normally, exit from the unwind-protect form proceeds as described above. It is permissible for a cleanup-form to contain a non-local exit from the unwind-protect form, subject to the following constraint:

An error shall be signaled if during execution of the cleanup-forms of an unwind-protect form, a non-local exit is executed to a destination which has been marked as invalid due to some other non-local exit that is already in progress (see §14.7.1) (error-id. control-error).

Note: Because ISLISP does not specify an interactive debugger, it is unspecified whether or how error recovery can occur interactively if programmatic handling fails. The intent is that if the ISLISP processor does not terminate abnormally, normal mechanisms for non-local exit (return-from, throw, or go) would be used as necessary and would respect these cleanup-forms.

Example:

(defun foo (x)
  (catch 'duplicates
    (unwind-protect (bar x)
      (for ((l x (cdr l)))
        (null l) 'unused)
      (remove-property (car l) 'label)))))
⇒ foo

(defun bar (l)
  (cond ((and (symbolp l) (property l 'label))
         (throw 'duplicates 'found))
        ((symbolp l) (setf (property l 'label) t))
        ((bar (car l)) (bar (cdr l)))
        (t nil)))
⇒ bar

(foo '(a b c)) ⇒ t
(property 'a 'label) ⇒ nil
(foo '(a b a c)) ⇒ found
(property 'a 'label) ⇒ nil

(defun test ()
  (catch 'outer (test2))) ⇒ test

(defun test2 ()
  (block inner
    (test3 (lambda ()
      (return-from inner 7))))
  ⇒ test2

(defun test3 (fun)
  (unwind-protect (test4) (funcall fun)))
  ⇒ test3

(defun test4 ()
  (throw 'outer 6)) ⇒ test4

(test) ⇒ an error shall be signaled

In the test example, the throw executed in test4 has as destination the catcher established in test. The unwind-protection in test3 intercepts the transfer of control and attempts to execute a return-from from the block in test2. Because this block is established within the dynamic extent of the destination catcher, an error is signaled.

15 Objects

15.1 Defining classes

The defclass defining form is used to define a new named class.

The definition of a class includes the following:

- The name of the new class.
- The list of the direct superclasses of the new class.
- A set of slot specifiers. Each slot specifier includes the name of the slot and zero or more slot options. A slot option pertains only to a single slot. A class definition must not contain two slot specifiers with the same name.
- A set of class options. Each class option pertains to the class as a whole.

The slot options and class options of the defclass defining form provide mechanisms for the following:

- Supplying a default initial value form for a given slot.
• Requesting that methods for generic functions be automatically generated for retrieving or storing slot values and inquiring whether a value is bound to the slot.

• Indicating that the metaclass of that class is to be other than the default.

```
(defclass class-name (sc-name*) (slot-spec*) class-opt*) → <symbol> defining operator
```

Where:

```
class-name ::= identifier
sc-name    ::= identifier
slot-spec  ::= slot-name | (slot-name slot-opt*)
slot-name  ::= identifier
slot-opt   ::= :reader reader-function-name |
              :writer writer-function-name |
              :accessor reader-function-name |
              :boundp boundp-function-name |
              :initform form |
              :initarg initarg-name
initarg-name ::= identifier
reader-function-name ::= identifier
writer-function-name ::= identifier
boundp-function-name ::= identifier
class-opt    ::= (:metaclass class-name) |
                (:abstractp abstract-flag)
abstract-flag ::= t | nil
```

The defclass defining form returns the symbol named class-name as its result.

The class-name argument is an identifier which becomes the name of the new class. The defining point of the class-name is the end of the defclass defining form.

Each superclass name argument sc-name is an identifier that specifies a direct superclass of the new class. The new class will inherit slots and their :reader or :writer or :accessor methods from each of its superclasses. See §15.1.3 for a definition of how slots are inherited, and §15.2.3 for a definition of how methods are inherited. No sc-name may appear more than once in super class names. It is a violation if the superclasses of any two direct superclasses sc-name have superclasses other than <standard-object> and <object> in common unless a metaclass other than <standard-class> is specified.

Each slot-spec argument is the name of the slot or a list consisting of the slot name followed by zero or more slot options. The slot-name argument is an identifier that is syntactically valid for use as an ISLISP variable name. No slot names may appear more than once in slot-spec.

The following slot options are available:

• The :reader slot option specifies that an unqualified method with the parameter profile ((x class-name)) is to be defined on the generic function named reader-function-name to retrieve the value of the given slot. The :reader slot option may be specified more than once for a given slot.
• The :writer slot option specifies that an unqualified method with the parameter profile ((y <object>) (x class-name)) is to be defined on the generic function named writer-function-name to store the value into the slot. The writer-function-name argument is an identifier. The :writer slot option may be specified more than once for a given slot.

• The :accessor slot option specifies that an unqualified method is to be defined on the generic function named reader-function-name to retrieve the value of the given slot. Furthermore, there is a generic function such that (self (reader-function-name x) y) is equivalent to calling this generic function with first argument y and second argument x. This generic function is extended by a method with the parameter profile ((y <object>) (x class-name)). The reader-function-name argument is an identifier. The :accessor slot option may be specified more than once for a given slot.

• The :boundp slot option specifies that an unqualified method with the parameter profile ((x class-name)) is to be defined on the generic function named boundp-function-name to test whether the given slot has been given a value. The :boundp slot option may be specified more than once for a given slot.

• The :initform slot option is used to provide a default initial value form to be used in the initialization of the slot. The :initform slot option may be specified once at most for a given slot. This form is evaluated every time it is used to initialize the slot. The lexical scope of the identifiers used in the initialization of the slot is the lexical scope of those identifiers in the defclass form. Note that the lexical scope refers both to variable and to function identifiers. In contrast, the current dynamic bindings used are those existing during activation of create. For more information, see §15.4.1.

• The :initarg slot option declares an initialization argument named initarg-name and specifies that this initialization argument initializes the given slot. If the initialization argument and associated value are supplied in the call to initialize-object, the value will be stored into the given slot and the slot’s :initform slot option, if any, is not evaluated. If none of the initialization arguments specified for a given slot has a value, the slot is initialized according to the :initform option, if specified. The consequences are undefined if more than one initialization argument for the same slot is supplied. For more information, see §15.4.1.

The generic functions, to which the methods created by the :reader, :writer, and :accessor slot options belong are called slot accessor.

No implementation is permitted to extend the syntax of defclass to allow (slot-name form) as an abbreviation for (slot-name :initform form).

Each class option is an option that refers to the class as a whole. The following class options are available:

• The :metaclass class option is used to specify that instances of the class being defined are to have a different metaclass than the default provided by the system, that is, different from the class <standard-class>. The class-name argument is the name of the desired metaclass. The :metaclass class option may be specified once at most. It is a violation if <built-in-class> is specified as the metaclass.

• The :abstractp class option is used to specify that the class is an abstract class. If this option is supplied and abstract-flag is t, create will signal an error if an attempt is made to create an instance of this class. If the option is unsupplied, or if abstract-flag is nil, the class is not an abstract class. It is a violation if the abstract-flag is supplied but is neither t nor nil.
The following rules of defclass hold for standard classes:

- The defclass defining form must be in the scope of any superclass identifier it refers to.
- All the superclasses of a class must be defined before an instance of the class can be made.
- Any reference to class-name as a parameter specializer in a defmethod form must be in the scope of class-name. That is, a defmethod form that names a class must textually follow the defclass form that defines that class.

An ISLISP processor may be extended to cover situations where these rules are not obeyed. These extensions shall be implementation defined.

Some slot options are inherited by a class from its superclasses, and some can be shadowed or altered by providing a local slot description. No class options are inherited. For a detailed description of how slots and slot options are inherited, see the section §15.1.3.

If no slot accessors are specified for a slot, the slot cannot be accessed.

When a class is defined, the order in which its direct superclasses are mentioned in the defining form is important. The new class has a local precedence order, which is a list consisting of the class followed by its direct superclasses in the order mentioned in its defclass defining form.

15.1.1 Determining the class precedence list

The defclass defining form for a class provides a total ordering on that class and its direct superclasses. This ordering is called the local precedence order. It is an ordered list of the class and its direct superclasses. The class precedence list for a class C is a total ordering on C and its superclasses that is consistent with the local precedence orders for each of C and its superclasses.

The class precedence list is always consistent with the local precedence order of each class in the list. The classes in each local precedence order appear within the class precedence list in the same order.

Let C₁, . . . , Cₙ be the direct superclasses of C in the order defined in the defclass defining form for C. Let P₁, . . . , Pₙ be the class precedence lists for C₁, . . . , Cₙ, respectively. Define P ⋅ Q on class precedence lists P and Q to be the two lists appended. Then the class precedence list for C is C ⋅ P₁ ⋅ . . . ⋅ Pₙ with duplicate classes removed by repeated application of the following rule: If a class appears twice in the resulting class precedence list, the leftmost occurrence is removed.

It is a violation if an attempt is made to define an instance of <standard-class> whose direct superclasses have class precedence lists with classes other than <standard-object> and <object> in common.

15.1.2 Accessing slots

Slots can be accessed by use of the slot accessors created or modified by the defclass defining form.
The defclass defining form provides syntax for generating methods to retrieve and store slot values. If a reader is requested, a method is automatically generated for retrieving the value of the slot, but no method for storing a value into it is generated. If a writer is requested, a method is automatically generated for storing a value into the slot, but no method for retrieving its value is generated. If an accessor is requested, a method for retrieving the value of the slot and a method for storing a value into the slot are automatically generated.

When a reader or writer is specified for a slot, the name of the generic function to which the generated method belongs is directly specified. If the name specified for the writer option is the identifier name, the name of the generic function for storing a value into the slot is the identifier name, and the generic function takes two arguments: the new value and the instance, in that order. If the name specified for the accessor option is the identifier name, the name of the generic function for retrieving the slot value is the identifier name, and storing a value into the slot can be done by using the syntax (setf (name instance) new-value).

A generic function created or modified by supplying reader, writer, or accessor slot options is a direct instance of <standard-generic-function>.

15.1.3 Inheritance of slots and slot options

The set of the names of all slots accessible in an instance of a class C is the union of the sets of names of slots defined by C and its superclasses. The structure of an instance is the set of names of slots in that instance.

In the simplest case, only one class among C and its superclasses defines a slot with a given slot name. If a slot is defined by a superclass of C, the slot is said to be inherited. The characteristics of the slot are determined by the slot specifier of the defining class.

In general, more than one class among C and its superclasses can define a slot with a given name. In such cases, only one slot with the given name is accessible in an instance of C, and the characteristics of that slot are a combination of the several slot specifiers, computed as follows:

- All the slot specifiers for a given slot name are ordered from most specific to least specific, according to the order in C's class precedence list. All references to the specificity of slot specifiers immediately below refer to this ordering.
- The default initial value form for a slot is the value of the :initform slot option in the most specific slot specifier that contains one. If no slot specifier contains an :initform slot option, the slot has no default initial value form.

The :reader, :writer, and :accessor slot options create methods rather than define the characteristics of a slot. Reader and writer methods are inherited in the sense described in the section §15.2.3.

15.2 Generic functions

A generic function is a function whose application behavior depends on the classes of the arguments supplied to it. A generic function object contains a set of methods, a lambda-list, a method combination type, and other information. The methods define the class-specific behavior.
and operations of the generic function; a method is said to \textit{specialize} a generic function. When invoked, a generic function executes a subset of its methods based on the classes of its arguments.

A generic function can be used in the same ways that an ordinary function can be used.

A \textit{method} consists of a method function, a lambda list, a sequence of \textit{parameter specializers} that specify when the given method is applicable, and a sequence of \textit{qualifiers} that is used by the method combination facility to distinguish among methods. Each required formal parameter of each method has an associated parameter specializer, and the method is invoked only on arguments that satisfy its parameter specializers.

The method combination facility controls the selection of methods, the order in which they are activated, and the value that is returned by the generic function. ISLISP provides a default method combination type but does not provide a facility for declaring new types of method combination.

Like an ordinary ISLISP function, a generic function takes arguments, performs a series of operations, and returns a value. An ordinary function has a single body of code that is always executed when the function is called. A generic function has a set of bodies of code of which a non-empty subset is selected for execution. The selected bodies of code and the manner of their combination are determined by the classes of the arguments to the generic function and by its method combination type.

\begin{verbatim}
(generic-function-p obj) \rightarrow boolean
\end{verbatim}

Returns \texttt{t} if \textit{obj} is a generic function; otherwise, returns \texttt{nil}. \textit{Obj} may be any ISLISP object.

### 15.2.1 Defining generic functions

Some forms specify the options of a generic function, such as the type of method combination it uses. These forms will be referred to as “forms that specify generic function options.” These forms are the \texttt{defgeneric} defining forms.

Some forms define methods for a generic function. These forms will be referred to as “method-defining forms.” These forms are the \texttt{defmethod} and \texttt{defclass} defining forms.

During preparation for execution, a \texttt{defmethod} form must be preceded by the \texttt{defgeneric} form for the generic function to be specialized. (Methods implicitly defined by \texttt{defclass} due to :reader, :writer, or :accessor options do not need a preceding \texttt{defgeneric}.)

\begin{verbatim}
(defgeneric \texttt{func-spec} lambda-list \{option | method-desc\} | \rightarrow \textless symbol\textgreater defining operator
\end{verbatim}

Where:

\begin{verbatim}
func-spec ::= identifier | (setf identifier)
lambda-list ::= \{var\* \{krest var\}\} | \{var\* [:krest var]\}
option ::= (:method-combination \{identifier | keyword\}) | (:generic-function-class class-name)
\end{verbatim}

52 PUBLIC DOMAIN
The `defgeneric` defining form is used to define a generic function and to specify options and declarations that pertain to a generic function as a whole.

It returns the generic function name `func-spec`.

The scope of the generic function identifier `func-spec` is the entire current toplevel scope.

The `lambda-list` argument is an ordinary function lambda-list.

The following options are provided. A given option may occur only once.

- The `:generic-function-class` option specifies that the generic function is to have a different class from the default provided by the system, that is, different from the class `<standard-generic-function>`. The `class-name` argument is the name of a class that can be the class of a generic function.

- The `:method-combination` option is followed by a symbol or keyword that names a type of method combination. The names of the built-in method combination types are `nil` and `standard`.

The `method-desc` arguments define methods that will belong to the generic function, as if defined by `defmethod`. The `method-qualifier` and `parameter-profile` arguments in a method description are the same as for `defmethod`. The `form` arguments specify the method body.

If no method descriptions are specified, a generic function with no methods is created. An error shall be signaled if a generic function is called and no methods apply.

The `lambda-list` argument of `defgeneric` specifies the shape of lambda-lists for the methods on this generic function. All methods on the resulting generic function must have parameter-profiles that are congruent with this shape. For further details on method congruence, see §15.2.2.2.

Implementations can extend `defgeneric` to include other implementation-defined options.

### 15.2.2 Defining methods for generic functions

```
(defmethod func-spec (method-qualifier* parameter-profile form*)
  \rightarrow <symbol>)
```

defining operator

Where:

```
func-spec ::= identifier | (self identifier)
method-qualifier ::= identifier | keyword
```

PUBLIC DOMAIN

53
The defmethod defining form defines a method on a generic function. It returns the generic function name func-spec.

A method-defining form contains the code that is to be executed when the arguments to the generic function cause the method that it defines to be invoked.

Preparing a method-defining form for execution causes one of the following cases:

- It is a violation if the given name func-spec already designates a generic function and this generic function contains a method that agrees with the new one on parameter specializers and qualifiers. For a definition of one method agreeing with another on parameter specializers and qualifiers, see the section §15.2.2.1.

- If the given name func-spec designates a generic function and this generic function does not contain a method that agrees with the new one on parameter specializers and qualifiers, the new method is added to the generic function.

- It is a violation if the defmethod defining form is in the scope of a func-spec identifier that does not designate a generic function.

- It is a violation if the given name func-spec does not exist in the current toplevel scope immediately containing the defmethod defining form. Furthermore, it is a violation if a defgeneric form for func-spec does not precede the method-defining form in the text unit being prepared for execution unless the method-defining form is a defclass.

The parameter-profile of the method being defined must be congruent with the lambda-list of the generic function. See §15.2.2.2 for a definition of congruence in this context.

Each method-qualifier argument is an object that is used as an attribute to the given method by method combination. A method qualifier is a non-nil symbol or keyword. The method combination type further restricts what a method qualifier may be. The standard method combination type allows for unqualified methods or methods whose sole qualifier is one of the keywords :before, :after, :around.

The parameter-profile argument is like an ordinary function lambda-list except that the names of required parameters can be replaced by specialized parameters. A specialized parameter is a list of the form (variable-name parameter-specializer-name). Only required parameters may be specialized. A parameter specializer name is an identifier that names a class. If no parameter specializer name is specified for a given required parameter, the parameter specializer defaults to the class named <object>.

The form arguments specify the method body.

No two methods with agreeing parameter specializers and qualifiers may be defined for the same generic function. See the section §15.2.2.1 for a definition of agreement in this context.

A method is not a function and cannot be invoked as a function.
15.2.2.1 Agreement on parameter specializers and qualifiers Two methods are said to agree with each other on parameter specializers and qualifiers if the following conditions hold:

1. Both methods have the same number of required parameters. Suppose the parameter specializers of the two methods are $P_1 \ldots P_{1,n}$ and $P_2 \ldots P_{2,n}$.

2. For each $1 \leq i \leq n$, $P_{1,i}$ agrees with $P_{2,i}$. The parameter specializer $P_{1,i}$ agrees with $P_{2,i}$ if $P_{1,i}$ and $P_{2,i}$ denote the same class. Otherwise $P_{1,i}$ and $P_{2,i}$ do not agree.

3. The qualifiers of both methods, if any, are the same.

The parameter specializers are derived from the parameter profiles as described above.

15.2.2.2 Congruent lambda-lists for all methods of a generic function These rules define the congruence of a set of lambda-lists, including the parameter profile of each method for a given generic function and the lambda-list specified for the generic function itself, if given.

1. Each lambda-list must have the same number of required parameters.

2. If any lambda-list mentions &rest or :rest, each lambda-list must mention &rest or :rest.

15.2.3 Inheritance of methods

A subclass inherits methods in the following sense: Any method applicable to all instances of a class is also applicable to all instances of any subclass of that class, since they are also instances of that class.

The inheritance of methods acts the same way regardless of whether the method was created by using the defmethod form or by using one of the defclass options that causes methods to be generated automatically.

15.3 Calling generic functions

When a generic function is called with particular arguments, it must determine the code to execute. This code is called the effective method for those arguments. The effective method is a combination of the applicable methods in the generic function, which might be some or all of the defined methods. An error shall be signaled if a generic function is called and no methods apply.

When the effective method has been determined, it is invoked with the same arguments that were passed to the generic function. Whatever value it returns is returned as the value of the generic function.

The effective method is determined by the following three-step procedure:

1. Select the applicable methods.
2. Sort the applicable methods by precedence order, putting the most specific method first.

3. Apply applicable methods according to the method combination.

15.3.1 Selecting the applicable methods

Given a generic function and a set of arguments, an \textit{applicable method} is a method for that generic function whose parameter specializers are satisfied by their corresponding arguments. The following definition specifies what it means for a method to be applicable and for an argument to satisfy a parameter specializer.

Let $\langle A_1, \ldots, A_n \rangle$ be the required arguments to a generic function in order. Let $\langle P_1, \ldots, P_n \rangle$ be the parameter specializers corresponding to the required parameters of the method $M$ in order. The method $M$ is \textit{applicable} when each $A_i$ \textit{satisfies} $P_i$. If $A_i$ is an instance of a class $C$, then it is said that $A_i$ \textit{satisfies} $P_i$ when $C = P_i$ or when $C$ is a subclass of $P_i$.

A method all of whose parameter specializers are the class named \texttt{<object>} is called a \textbf{default method}; it is always applicable but might be shadowed by a more specific method.

Methods can have \textbf{qualifiers}, which give the method combination procedure a way to distinguish among methods. A method that has one or more qualifiers is called a \textbf{qualified method}. A method with no qualifiers is called an \textbf{unqualified method}. Any object after ::\texttt{method} and before the first list in \texttt{method-desc} is regarded as a qualifier, but only non-nil symbols and keywords are accepted as qualifiers. The qualifiers defined by standard method combination are keywords.

15.3.2 Sorting the applicable methods

To compare the precedence of two methods, their parameter specializers are examined in order. The examination order is from left to right.

The corresponding parameter specializers from each method are compared. When a pair of parameter specializers are equal, the next pair are compared for equality. If all corresponding parameter specializers are equal, the two methods must have different qualifiers; in this case, either method can be selected to precede the other.

If some corresponding parameter specializers are not equal, the first pair of parameter specializers that are not equal determines the precedence. The more specific of the two methods is the method whose parameter specializer appears earlier in the class precedence list of the corresponding argument. Because of the way in which the set of applicable methods is chosen, the parameter specializers are guaranteed to be present in the class precedence list of the class of the argument.

The resulting list of applicable methods has the most specific method first and the least specific method last.

15.3.3 Applying methods

In general, the effective method is some combination of the applicable methods. It is defined by a form that contains calls to some or all of the applicable methods, returns the value that will be
returned as the value of the generic function, and optionally makes some of the methods accessible by means of call-next-method. This form is the body of the effective method; it is augmented with an appropriate lambda-list to make it a function.

The role of each method in the effective method is determined by its method qualifiers and the specificity of the method. A qualifier serves to mark a method, and the meaning of a qualifier is determined by the way that these marks are used by this step of the procedure. An error shall be signaled if an applicable method has an unrecognized qualifier.

ISLISP provides two method combination types. To specify that a generic function is to use one of these method combination types, the name of the method combination type is given as the argument to the :method-combination option to defgeneric.

The names of the method combination types are nil and standard.

15.3.3.1 Simple method combination In the simple case—the nil method combination type where all applicable methods are primary methods—the effective method calls the most specific method. That method can call the next most specific method by using call-next-method. The method that call-next-method calls is referred to as the next method. The predicate next-method-p tests whether a next method exists. An error shall be signaled if call-next-method is called and there is no next most specific method.

15.3.3.2 Standard method combination Standard method combination is used if no other type of method combination is specified or if the method combination standard is specified.

Primary methods define the main action of the effective method, while auxiliary methods modify that action in one of three ways. A primary method has no method qualifiers. An auxiliary method is a method whose method qualifier is :before, :after, or :around.

- A :before method has the keyword :before as its qualifier. A :before method specifies code that is to be run before any primary methods.
- An :after method has the keyword :after as its qualifier. An :after method specifies code that is to be run after primary methods.
- An :around method has the keyword :around as its qualifier. An :around method specifies code that is to be run instead of other applicable methods but which is able to cause some of them to be run.

The semantics of standard method combination is as follows:

- If there are any :around methods, the most specific :around method is called. It supplies the value of the generic function.

- Inside the body of an :around method, call-next-method can be used to call the next method. When the next method returns, the :around method can execute more code, perhaps based on the returned value. An error shall be signaled if call-next-method is used and there is no applicable method to call. The function next-method-p can be used to determine whether a next method exists.
• If an :around method invokes call-next-method, the next most specific :around method is called, if one is applicable. If there are no :around methods or if call-next-method is called by the least specific :around method, the other methods are called as follows:

• All the :before methods are called, in most-specific-first order. Returned values are ignored. An error shall be signaled if call-next-method is used in a :before method.

• The most specific primary method is called. Inside the body of a primary method, the form call-next-method can be used to call the next most specific primary method. When that method returns, the previous primary method can execute more code, perhaps based on the returned value. An error shall be signaled if call-next-method is used and there are no more applicable primary methods. The next-method-p function can be used to determine whether a next method exists. If call-next-method is not used, only the most specific primary method is called.

• All the :after methods are called in most-specific-last order. Returned values are ignored. An error shall be signaled if call-next-method is used in an :after method.

• If no :around methods were invoked, the most specific primary method supplies the value returned by the generic function. The value returned by the invocation of call-next-method in the least specific :around method is that returned by the most specific primary method.

An error shall be signaled if there is an applicable method but no applicable primary method while using standard method combination.

The :before methods are run in most-specific-first order while the :after methods are run in least-specific-first order. The design rationale for this difference can be illustrated with an example. Suppose class $C_1$ modifies the behavior of its superclass, $C_2$, by adding :before and :after methods. Whether the behavior of the class $C_2$ is defined directly by methods on $C_2$ or is inherited from its superclasses does not affect the relative order of invocation of methods on instances of the class $C_1$. Class $C_1$'s :before method runs before all of class $C_2$'s methods. Class $C_1$'s :after method runs after all of class $C_2$'s methods.

By contrast, all :around methods run before any other methods run. Thus a less specific :around method runs before a more specific primary method.

If only primary methods are used and if call-next-method is not used, only the most specific method is invoked; that is, more specific methods shadow more general ones.

### 15.3.4 Calling more general methods

<table>
<thead>
<tr>
<th>(call-next-method)</th>
<th>→ &lt;object&gt;</th>
<th>local function</th>
</tr>
</thead>
</table>

The call-next-method function can be used within the body of a method to call the next method.

It returns the value returned by the method it calls.

The type of method combination used determines which methods can invoke call-next-method and what is the next method to be called.
In the case of simple method combination where the method combination type is nil the next method is the next most specific method.

The standard method combination type allows call-next-method to be used within primary methods and :around methods. The standard method combination type defines the next method as specified in §15.3.3.2.

call-next-method passes the current method's original arguments to the next method. Neither using setq nor rebinding variables with the same names as parameters of the method affects the values call-next-method passes to the method it calls. The call-next-method function returns the value returned by the method it calls. After call-next-method returns, further computation is possible. The next-method-p function can be used to test whether there is a next method.

The functional binding of call-next-method is lexical within the body of the method-defining form; i.e., it is as if it were established by labels. The function object to which the binding refers has indefinite extent.

An error shall be signaled if call-next-method is used in methods that do not support it. An error shall be signaled if call-next-method is executed and there is no next method.

\[
\text{(next-method-p) \rightarrow boolean} \quad \text{local function}
\]

The next-method-p function can be used within the body of a method defined by a method-defining form to determine whether a next method exists. The next-method-p function takes no arguments and returns t or nil.

The functional binding of next-method-p is lexical within the body of the method-defining form; i.e., it is as if it were established by labels. The function object to which the binding refers has indefinite extent.

15.4 Object creation and initialization

\[
\text{(create class \{initary initval\}*) \rightarrow \langle object\rangle} \quad \text{generic function}
\]

The function create creates and returns a new instance of a class. The argument is a class object.

The initialization of a new instance consists of several distinct steps, including the following: allocating storage for the instance, filling slots with values, and executing user-supplied methods that perform additional initialization. The last two steps of create are implemented by the generic function initialize-object to provide a mechanism for customizing those steps. The initialization arguments (the initarys and initvals) are given as a single list argument to initialize-object. The instance returned by create is the new instance, which has been modified and returned by initialize-object.
15.4.1 Initialize-object

The generic function initialize-object is called by create to initialize a newly created instance. It uses standard method combination. Methods for initialize-object can be defined on user-defined classes in order to augment or override the system-supplied slot-filling mechanisms (described below).

During initialization, initialize-object is invoked after a new instance whose slots are unbound has been created.

The generic function initialize-object is called with the new instance. There is a system-supplied primary method for initialize-object whose parameter specializer is the class <standard-object>. This method fills in the slots according to the initialization arguments provided and according to the :initform forms for the slots as follows:

- If the slot already has a value, no attempt is made to change that value.
- If an initialization argument and value pair for the slot was provided among the initialization arguments, the slot is initialized with the value from that pair. The name of the initialization argument for a slot is declared by the :initarg option to slots in defclass. The consequences are undefined if more than one initialization argument for the same slot is supplied.
- If the slot has a default initial value form (see defclass), that form is evaluated in the lexical environment in which that form was established and in the current dynamic environment. The result of the evaluation is an object which becomes the value of the slot.
- Otherwise, the slot is left uninitializated.

(initialize-object instance initialization-arguments) → <object>  

The generic function initialize-object is called by create to initialize a newly created instance. The generic function initialize-object is called with the new instance and a list of initialization arguments.

The system-supplied primary method on initialize-object initializes the slots of the instance with values according to the initialization-arguments (an alternating list of initialization argument keywords and values) and the :initform forms of the slots.

The instance argument is the object to be initialized. The modified instance is returned as the result. Programmers can define methods for initialize-object to specify actions to be taken when an instance is initialized. If only :after methods are defined, they will be run after the system-supplied primary method for initialization and therefore will not interfere with the default behavior of initialize-object. The consequences are undefined if a programmer-defined primary method for this generic function does not return instance.

15.5 Class enquiry

(class-of obj) → <class>  

function
Returns the class of which the given obj is a direct instance. obj may be any ISLISP object.

\[
\text{(instancep obj class)} \rightarrow \text{boolean}
\]

function

Returns t if obj is an instance (directly or otherwise) of the class class; otherwise, returns nil. obj may be any ISLISP object. An error shall be signaled if class is not a class object (error-id. domain-error).

\[
\text{(subclassp class1 class2)} \rightarrow \text{boolean}
\]

function

Returns t if the class class1 is a subclass of the class class2; otherwise, returns nil. An error shall be signaled if either class1 or class2 is not a class object (error-id. domain-error).

\[
\text{(class class-name)} \rightarrow \text{<class>}
\]

special operator

Returns the class object that corresponds to the class named class-name.

16 Macros

Macros are a feature to extend the language syntactically. A macro is an abstraction for surface transformations. Because ISLISP texts (e.g., function definitions) can be represented internally by objects in ISLISP, the surface transformations can be described by means of list processing. Forms are represented by conses or other objects and a macro describes a transformation function from one group of objects onto another.

Macros can be internally defined by expander functions which implement the transformation from one group of objects to another. The operation of an expander functions is specified by a defmacro defining form.

An expander receives a form as argument and returns a different form as value. The primary activity of an expander is to create sets of nested lists; for this purpose, the backquote facility is provided.

Macros are expanded at preparation time. No runtime information is available.

The set of usable operations is restricted to simple data structure creation and manipulation; those operations are forbidden that cause side-effects to the environment (such as I/O to the terminal), to externally accessible data structure (such as a modification to the property list of a symbol), or to the macro form itself.

Macro definitions are allowed only at toplevel. Redefinition (i.e., multiple definition) of macros is forbidden. A macro’s definition must textually precede any use of that macro during preparation for execution.

The result of expanding a macro form is another form. If that form is a macro form, it is expanded by the same mechanism until the result is not a macro form.
When a toplevel form is a macro form, its resulting macro expansion is also considered to be a
toplevel form.

A macro form can appear as the place specified in a setf special form. See setf on page 34.

```
(defmacro macro-name lambda-list form*) -> <symbol>
```
defining operator

Defines a named (toplevel) macro. No implicit block with the macro name is established when
the macro-expansion function is invoked. macro-name must be an identifier whose scope is the
current toplevel scope in which the defmacro form appears. lambda-list is as defined in page 23.
The definition point of macro-name is the closing parenthesis of the lambda-list.

Example:

```
(defmacro caar(x) (list 'car (list 'car x)))
≡ caar
```

`form` -> <object>  
`form` -> <object>  
`form` -> <object>  

or quasiquote constructs a list structure. quasiquote, like quote, returns its argument
unevaluated if no commas or the syntax , (unquote) or ,@ (unquote-splicing) appear within the
form.

, (unquote) syntax is valid only within ` (quasiquote) expressions. When appearing within a
quasiquote the form is evaluated and its result is inserted into the quasiquote structure instead of
the unquote form.

,@ (unquote-splicing) is also syntax valid only within ` expressions. When appearing within a
quasiquote the expression form must evaluate to a list. The elements of the list are spliced into
the enclosing list in place of the unquote-splicing form sequence.

Quasiquote forms may be nested. Substitutions are made only for unquoted expressions
appearing at the same nesting level, which increases by one inside each successive quasi quotation
and decreases by one inside each unquotation.

Example:

```
`(list ,(+ 1 2) 4)
≡ (list 3 4)
(let ((name 'a) `(list name ,name ',name))
  `(a ,(+ 1 2) ,(create-list 3 'x) b)
  ⇒ (a 3 x x b)
  `((foo ,(+ 10 3)) ,(cdr 'c) ,(car 'cons))
  ⇒ ((foo 7) . cons)
  `(a ,(b ,(+ 1 2) ,(foo ,(+ 1 3) d) e) f)
```
17 Declarations and coercions

(\text{the class-name form}) \rightarrow \langle \text{object} \rangle \quad \text{special operator}

(\text{assure class-name form}) \rightarrow \langle \text{object} \rangle \quad \text{special operator}

These forms evaluate \text{form}. If \text{form} returns, the returned value is returned by the \text{the} or \text{assure} form. In addition, these forms specify that the value of \text{form} is of the class specified by \text{class-name} (which must be the name of an existing class).

In a \text{the} special form, the consequences are undefined if the value of \text{form} is not of the class or a subclass of the class designated by \text{class-name}. In an \text{assure} special form, an error shall be signaled if the value of \text{form} is not of the class or a subclass of the class designated by \text{class-name} (error-id. domain-error).

Example:

(\text{the} \langle \text{integer} \rangle 10) \quad \Rightarrow 10
(\text{the} \langle \text{number} \rangle 10) \quad \Rightarrow 10
(\text{the} \langle \text{float} \rangle 10) \quad \text{the consequences are undefined}
(\text{assure} \langle \text{integer} \rangle 10) \quad \Rightarrow 10
(\text{assure} \langle \text{number} \rangle 10) \quad \Rightarrow 10
(\text{assure} \langle \text{float} \rangle 10) \quad \text{an error shall be signaled}

\text{(convert obj class-name)} \rightarrow \langle \text{object} \rangle \quad \text{special operator}

Returns an object of class \text{class-name} which corresponds to the object \text{obj} according to one of the following projections, called a coercion function. The table shows \text{obj} along the left-hand column and \text{class-name} along the top row (with \text{<>}'s in class names omitted here only for textual brevity):

<table>
<thead>
<tr>

</tbody>
</table>
Legend:

= This is the identity function
X This coercion shall be provided

X(2) An error shall be signaled if this coercion is attempted and the string does not contain the textual representation of a number of the target class. In all other respects, this is the same as parse-number.
X(5) This may be the same as the ^D format directive.
X(6) This may be the same as the ^G format directive.
X(7) This is the identity if strings are vectors in the implementation.
I This coercion shall be provided, but its definition is implementation defined.
I(3) This coercion shall be provided, but its definition is implementation defined. The coercion depends on the implementation's neutral alphabetic characters (see §18.1.2).

- An error shall be signaled if this coercion is attempted.
  -(1) Programmers requiring this kind of functionality may wish to consider instead using one of the functions, floor, ceiling, round, or truncate.
  -(4) Programmers requiring this kind of functionality may wish to consider instead using the following: (create-string 1 obj)

If an implementation provides implementation-defined classes, it may also provide implementation-defined coercions for the names of those classes using convert.

Example:

(convert 3 <float>) ⇒ 3.0
(convert "abc" <general-vector>) ⇒ #\(#\a\ #\b\ #\c\)
(convert #(a b) <list>) ⇒ (a b)

18 Symbol class

A symbol (an instance of class <symbol>) is an object. Symbols can be named or unnamed. A symbol's name is sometimes called a print name because it is used to identify the symbol during reading and printing. Symbols can have associated properties.

\[
\text{(symbolp \ obj)} \rightarrow \text{boolean}
\]

function

Returns t if \obj\ is a symbol (instance of class <symbol>); otherwise, returns nil. The \obj\ may be any ISLisp object.
Example:

(symbolp 'a) ⇒ t
(symbolp "a") ⇒ nil
(symbolp #\a) ⇒ nil
(symbolp 't) ⇒ t
(symbolp t) ⇒ t
(symbolp 'nil) ⇒ t
(symbolp nil) ⇒ t
(symbolp '()) ⇒ t
(symbolp '*pi*) ⇒ t
(symbolp *pi*) ⇒ nil

18.1 Symbol names

Symbols can be either named or unnamed.

There is a mapping from names to symbols. Distinct symbols (symbols that are not eq) always have distinct names. No such mapping is defined for unnamed symbols.

The name of a symbol is represented as a string.

18.1.1 Notation for symbols

The constituent characters of a symbol's name are described in §6.

A named symbol is denoted by its print name enclosed within the vertical bars ("|"). However, the enclosing vertical bars are not necessary if the symbol satisfies the following conditions:

1. The symbol's print name consists only of neutral alphabetic characters (see §18.1.2) or the following additional characters:

   0 1 2 3 4 5 6 7 8 9 + - < > / * = ? _ ! $ % [ ] - { } -

   (This set may have additional implementation-defined characters.)

2. The first character of the symbol's print name is a neutral alphabetic character or one of the following characters:

   < > / * = ? _ ! $ % [ ] - { } -

   (This set may have additional implementation-defined characters.)

In addition, the following are the names of symbols that can be written without enclosing vertical bars:

   + - 1+ 1-
If the symbol name contains a vertical bar, the vertical bar must be preceded by a backslash "\".
If the symbol name contains a backslash, the backslash must be preceded by another backslash.
For example, "\\\\\\\" denotes a symbol whose name is a 5 character string containing
backslash, backslash, vertical bar, backslash, vertical bar.

Note: All required symbols can be written without vertical bars.

It is implementation defined whether the names of symbols can contain colon (:) or ampersand (&). Consequently, whether &rest and keywords (e.g., :rest, :before, and :after) are
represented as symbols or something else is implementation defined.

18.1.2 Alphabetic case in symbol names

If the enclosing vertical bars are omitted, the case of alphabetic characters in a symbol is
translated by the reader to a canonical case that is used internally. Therefore, for example, each
of the following denotes the same symbol in all implementations:

    foo  fo0  f0o  F00  Fo0  F0o  F00

Internally, alphabetic case in a symbol’s print name is maintained, and is significant. For
example, [F00] and [foo] are not the same symbol in any implementation. However, the reader
canonicalizes the case of symbols whose names are not written enclosed by vertical bars. So foo
and F00 both represent the same symbol, but it is implementation defined whether that symbol
is [foo] or [F00].

Specifically, each implementation has an implementation-defined attribute called its neutral
alphabetic case, which is either “lowercase” or “uppercase.” If the neutral alphabetic case of
an implementation is lowercase, the neutral alphabetic characters for that implementation are defined to be as follows:

    a b c d e f g h i j k l m n o p q r s t u v w x y z

Otherwise (if the neutral alphabetic case of an implementation is uppercase), the neutral
alphabetic characters for that implementation are defined to be as follows:

    A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

Continuing again with the above example, if the neutral alphabetic case of an implementation is
lowercase, foo, F00 and [foo] denote the same symbol; otherwise, foo, F00 and [F00] denote
the same symbol.

An implementation may extend the set of neutral alphabetic characters to include additional
implementation-defined characters.

18.1.3 nil and ()

The symbol nil, which represents both the false value and the empty list, can also be denoted by ().
18.2 Symbol properties

A **property** of a symbol is a named association between a **property indicator** and a **property value**. A symbol `s` is said to have a property `p` if a property indicator `p` is associated with `s`.

```
(property symbol property-name [obj]) → <object>  function
```

Returns the value of the property named `property-name` associated with the symbol `symbol`. If `symbol` has no property named `property-name`, `obj` (which defaults to `nil`) is returned.

An error shall be signaled if either `symbol` or `property-name` is not a symbol (error-id. `domain-error`). `obj` may be any ISLISP object

**Example:**

```
(property 'zeus 'daughter) ⇒ athena
```

```
(setf (property symbol property-name) obj) → <object>  special form
(set-property obj symbol property-name) → <object>  function
```

Causes `obj` to be the new value of the property named `property-name` associated with the symbol `symbol`. If the property named `property-name` already exists, its corresponding property value is replaced; otherwise, a new property is created. `obj` is returned.

An error shall be signaled if either `symbol` or `property-name` is not a symbol (error-id. `domain-error`). `obj` may be any ISLISP object

**Example:**

```
(setf (property 'zeus 'daughter) 'athena)
⇒ athena
(set-property 'athena 'zeus 'daughter)
⇒ athena
```

```
(remove-property symbol property-name) → <object>  function
```

Removes the property `property-name` associated with `symbol` and returns the property value of the removed property if there is such a property. If there is no such property, `nil` is returned.

An error shall be signaled if either `symbol` or `property-name` is not a symbol (error-id. `domain-error`).

**Example:**
(remove-property 'zeus 'daughter)  ⇒  athena

18.3 Unnamed symbols

\[
\text{\texttt{(gensym)} } \rightarrow \text{\texttt{<symbol>} } \quad \text{\texttt{function}}
\]

Returns an unnamed symbol. gensym is useful for writing macros. It is impossible for an identifier to name an unnamed symbol.

Example:

\[
\begin{align*}
\text{(defmacro twice (x)} \\
\quad (\text{let ((v (gensym)))} \\
\quad \quad \quad \text{''(let ((,v ,x)) (+ ,v ,v)))} \quad \Rightarrow \text{twice} \\
\text{(twice 5)} \quad \Rightarrow \text{10}
\end{align*}
\]

19 Number class

The class \texttt{<number>} has the disjoint subclasses \texttt{<float>} and \texttt{<integer>}.

19.1 Number class

\[
\text{\texttt{(numberp obj)} } \rightarrow \text{\texttt{boolean} } \quad \text{\texttt{function}}
\]

Returns t if \texttt{obj} is a number (instance of class \texttt{<number>}); otherwise, returns \texttt{nil}. The \texttt{obj} may be any ISLisp object.

Example:

\[
\begin{align*}
\text{(numberp 3)} \quad \Rightarrow \text{t} \\
\text{(numberp -0.3)} \quad \Rightarrow \text{t} \\
\text{(numberp '(a b c))} \quad \Rightarrow \text{nil} \\
\text{(numberp "17")} \quad \Rightarrow \text{nil}
\end{align*}
\]

\[
\text{(parse-number string)} \rightarrow \text{<number>} \quad \text{function}
\]
The characters belonging to string are scanned (as if by read) and if the resulting lexeme is the
textual representation of a number, the number it represents is returned.

An error shall be signaled if string is not a string (error-id. domain-error). An error shall be
signaled if string is not the textual representation of a number (error-id. cannot-parse-number).

Example:

\[
\begin{align*}
\text{(parse-number "123.34")} & \Rightarrow 123.34 \\
\text{(parse-number "#XFACE")} & \Rightarrow 64206 \\
\text{(parse-number "}-37."\text{)} & \text{an error shall be signaled} \\
\text{(parse-number "}-5"\text{)} & \text{an error shall be signaled} \\
& \text{since floating-point number lexemes have} \\
& \text{at least one mantissa digit before and at least} \\
& \text{one mantissa digit after the decimal point.}
\end{align*}
\]

\[
\begin{align*}
(= \ x_1 \ x_2) & \to \text{boolean} \\
\text{function}
\end{align*}
\]

Returns t if \( x_1 \) has the same mathematical value as \( x_2 \); otherwise, returns nil. An error shall be
signaled if either \( x_1 \) or \( x_2 \) is not a number (error-id. domain-error).

Note: = differs from eql because = compares only the mathematical values of its arguments, whereas
eql also compares the representations.

Example:

\[
\begin{align*}
(= \ 3 \ 4) & \Rightarrow \text{nil} \\
(= \ 3 \ 3.0) & \Rightarrow \text{t} \\
(= \ \text{(parse-number "134.54")} \ \text{134.54}) & \Rightarrow \text{t} \\
(= \ 0.0 \ \text{-0.0}) & \Rightarrow \text{t}
\end{align*}
\]

\[
\begin{align*}
(/= \ x_1 \ x_2) & \to \text{boolean} \\
\text{function}
\end{align*}
\]

Returns t if \( x_1 \) and \( x_2 \) have mathematically distinct values; otherwise, returns nil. An error
shall be signaled if either \( x_1 \) or \( x_2 \) is not a number (error-id. domain-error).

Example:

\[
\begin{align*}
(/= \ 3 \ 4) & \Rightarrow \text{t} \\
(/= \ 3 \ 3.0) & \Rightarrow \text{nil} \\
(/= \ \text{(parse-number "134.54")} \ \text{134.54}) & \Rightarrow \text{nil}
\end{align*}
\]
ISLISP Working Draft 22.0

\(\geq x_1 \, x_2\) \rightarrow boolean  
\(\leq x_1 \, x_2\) \rightarrow boolean  
\(> x_1 \, x_2\) \rightarrow boolean  
\(< x_1 \, x_2\) \rightarrow boolean

\(\geq\) returns t if \(x_1\) is greater than or \(=\) \(x_2\).  
\(\leq\) returns t if \(x_1\) is less than or \(=\) \(x_2\).  
\(>\) returns t if \(x_1\) is greater than \(x_2\).  
\(<\) returns t if \(x_1\) is less than \(x_2\).

The mathematical values of the arguments are compared. An error shall be signaled if either \(x_1\) or \(x_2\) is not a number (error-id: domain-error).

Example:

\[
\begin{align*}
(> \, 2 \, 2) & \Rightarrow \text{nil} \\
(> \, 2.0 \, 2) & \Rightarrow \text{nil} \\
(> \, 2 \, -10) & \Rightarrow \text{t} \\
(> \, 100 \, 3) & \Rightarrow \text{t} \\
(< \, 2 \, 2) & \Rightarrow \text{nil} \\
(< \, 1 \, 2) & \Rightarrow \text{t} \\
(>\leq \, 2 \, 2) & \Rightarrow \text{t} \\
(>\leq \, 2.0 \, 2) & \Rightarrow \text{t} \\
(>\leq \, -1 \, 2) & \Rightarrow \text{nil} \\
(>\leq \, -1 \, 2) & \Rightarrow \text{t} \\
(>\leq \, 2 \, -1) & \Rightarrow \text{nil}
\end{align*}
\]

In the remaining definitions in this section, any noted coercion to \(<\text{float}>\) is done as if by \text{float} or by (convert \(z\) \(<\text{float}>\)).

\(\text{(+} \, x^+\) \rightarrow <\text{number}>  
\(\text{(*} \, x^+\) \rightarrow <\text{number}>

The functions \(+\) and \(*\) return the sum and the product, respectively, of their arguments. If all arguments are integers, the result is an integer. If any argument is a float, the result is a float. When given no arguments, \(+\) returns \(0\) and \(*\) returns \(1\). An error shall be signaled if any \(x\) is not a number (error-id: domain-error).

Example:

\[
\begin{align*}
(+ \, 12 \, 3) & \Rightarrow 15 \\
(+ \, 1.2 \, 3) & \Rightarrow 6 \\
(+ \, 12 \, 3.0) & \Rightarrow 15.0 \\
(+ \, 4 \, 0.0) & \Rightarrow 4.0 \\
(+\,) & \Rightarrow 0 \\
(* \, 12 \, 3) & \Rightarrow 36 \\
(* \, 12 \, 3.0) & \Rightarrow 36.0 \\
(* \, 4.0 \, 0) & \Rightarrow 0.0 \\
(* \, 2 \, 3 \, 4) & \Rightarrow 24 \\
(*\,) & \Rightarrow 1
\end{align*}
\]
\((- x^+) \rightarrow \langle\text{number}\rangle\) \hspace{1cm} \text{function}

Given one argument, \(x\), this function returns its additive inverse. An error shall be signaled if \(x\) is not a number (error-id. \texttt{domain-error}).

If an implementation supports a \(-0.0\) that is distinct from \(0.0\), then \((- 0.0)\) returns \(-0.0\); in implementations where \(-0.0\) and \(0.0\) are not distinct, \((- 0.0)\) returns \(0.0\).

**Example:**

\[
\begin{align*}
(- 1) & \Rightarrow -1 \\
(- -4.0) & \Rightarrow 4.0 \\
(- 4.0) & \Rightarrow -4.0 \\
(eq\ (- 0.0) -0.0) & \Rightarrow t \\
(eq\ (- -0.0) 0.0) & \Rightarrow t
\end{align*}
\]

Given more than one argument, \(x_1 \ldots x_n\), \(-\) returns their successive differences, \(x_1 - x_2 - \ldots - x_n\). An error shall be signaled if any \(x\) is not a number (error-id. \texttt{domain-error}).

**Example:**

\[
\begin{align*}
(- 1 2) & \Rightarrow -1 \\
(- 92 43) & \Rightarrow 49 \\
(- 2.3 -3.0) & \Rightarrow 5.3 \\
(- 0.0 0.0) & \Rightarrow 0.0 \\
(- 3 4 5) & \Rightarrow -6
\end{align*}
\]

\((\text{quotient dividend divisor}^+) \rightarrow \langle\text{number}\rangle\) \hspace{1cm} \text{function}

\((\text{reciprocal } x) \rightarrow \langle\text{number}\rangle\) \hspace{1cm} \text{function}

The function \texttt{reciprocal} returns the reciprocal of its argument \(x\); that is, \(1/x\). An error shall be signaled if \(x\) is zero (error-id. \texttt{division-by-zero}).

The function \texttt{quotient}, given two arguments \texttt{dividend} and \texttt{divisor}, returns the quotient of those numbers. The result is an integer if \texttt{dividend} and \texttt{divisor} are integers and \texttt{divisor} evenly divides \texttt{dividend}, otherwise it will be a float.

Given more than two arguments, \texttt{quotient} operates iteratively on each of the \texttt{divisor}_1 \ldots \texttt{divisor}_n as in \texttt{dividend/divisor}_1/\ldots/divisor_n. The type of the result follows from the two-argument case because the three-or-more-argument \texttt{quotient} can be defined as follows:

\[
\begin{align*}
(\text{quotient dividend divisor}_1 \text{ divisor}_2 \ldots) & \equiv (\text{quotient (quotient dividend divisor}_1 \text{ divisor}_2 \ldots))
\end{align*}
\]
An error shall be signaled if \textit{dividend} is not a number (error-id: \textit{domain-error}). An error shall be signaled if any \textit{divisor} is not a number (error-id: \textit{domain-error}). An error shall be signaled if any \textit{divisor} is zero (error-id: \textit{division-by-zero}).

Example:

\begin{verbatim}
(reciprocal 2)  \Rightarrow  0.5
(quotient 10 5) \Rightarrow  2
(quotient 1 2)  \Rightarrow  0.5
(quotient 2 -0.5) \Rightarrow -4.0
(quotient 0 0.0) \textit{an error shall be signaled}
(quotient 2 3 4) \Rightarrow 0.1666666666666666
\end{verbatim}

\begin{verbatim}
(max x\, y) \rightarrow <number>  \quad \textit{function}
(min x\, y) \rightarrow <number>  \quad \textit{function}
\end{verbatim}

The function \textit{min} returns the least (closest to negative infinity) of its arguments. The comparison is done by \textless{}.

The function \textit{max} returns the greatest (closest to positive infinity) of its arguments. The comparison is done by \textgreater{}.

An error shall be signaled if any \textit{x} is not a number (error-id: \textit{domain-error}).

Example:

\begin{verbatim}
(max -5 3)  \Rightarrow  3
(max 2.0 3) \Rightarrow  3
(max 2.2 0.2) \Rightarrow  2.2 \, or \, 2.0 \quad \textit{(implementation-defined)}
(max 1.5 2 4 3) \Rightarrow  5
(min 3 1)  \Rightarrow  1
(min 1 2.0) \Rightarrow  1
(min 2 2.0) \Rightarrow  2.0 \, or \, 2.0 \quad \textit{(implementation-defined)}
(min 1 5 2 4 3) \Rightarrow  1
\end{verbatim}

\begin{verbatim}
(abs x) \rightarrow <number>  \quad \textit{function}
\end{verbatim}

The function \textit{abs} returns the absolute value of its argument. An error shall be signaled if \textit{x} is not a number (error-id: \textit{domain-error}).

Example:

\begin{verbatim}
(abs -3)  \Rightarrow  3
(abs 2.0) \Rightarrow  2.0
(abs -0.0) \Rightarrow  0.0
\end{verbatim}
\[(\exp x) \to <\text{number}>\]  

function

Returns \(e\) raised to the power \(x\), where \(e\) is the base of the natural logarithm. An error shall be signaled if \(x\) is not a number (error-id. domain-error).

Example:

\[
\begin{array}{ll}
(\exp 1) & \Rightarrow 2.718281828459045 \\
(\exp 2) & \Rightarrow 7.38905609893065 \\
(\exp 1.23) & \Rightarrow 3.4212295362896734 \\
(\exp 0) & \Rightarrow 1 \text{ or } 1.0 \text{ (implementation-defined)} \\
\end{array}
\]

\[(\log x) \to <\text{number}>\]  

function

Returns the natural logarithm of \(x\). An error shall be signaled if \(x\) is not a positive number (error-id. domain-error).

Example:

\[
\begin{array}{ll}
(\log 2.718281828459045) & \Rightarrow 1.0 \\
(\log 10) & \Rightarrow 2.302585092994046 \\
(\log 1) & \Rightarrow 0 \text{ or } 0.0 \text{ (implementation-defined)} \\
\end{array}
\]

\[(\exp x_1 x_2) \to <\text{number}>\]  

function

Returns \(x_1\) raised to the power \(x_2\). The result will be an integer if \(x_1\) is an integer and \(x_2\) is a non-negative integer. An error shall be signaled if \(x_1\) is zero and \(x_2\) is negative, or if \(x_1\) is zero and \(x_2\) is a zero float, or if \(x_1\) is negative and \(x_2\) is not an integer.

Example:

\[
\begin{array}{ll}
(\exp 2 3) & \Rightarrow 8 \\
(\exp -100 2) & \Rightarrow 10000 \\
(\exp 4 -2) & \Rightarrow 0.0625 \\
(\exp 0.5 2) & \Rightarrow 0.25 \\
(\exp x 0) & \Rightarrow 1 \text{ if } x \text{ is an integer} \\
(\exp x 0) & \Rightarrow 1.0 \text{ if } x \text{ is a float} \\
(\exp -0.25 -1) & \Rightarrow -4.0 \\
(\exp 100 0.5) & \Rightarrow 10.0 \\
(\exp 100 -1.5) & \Rightarrow 0.001 \\
(\exp x 0.0) & \Rightarrow 1.0 \text{ if } x \text{ is a positive float} \\
(\exp 0.0 0.0) & \text{ an error shall be signaled} \\
\end{array}
\]
(sqrt x) → <number> function

Returns the non-negative square root of x. An error shall be signaled if x is not a non-negative number (error-id: domain-error).

Example:

(sqrt 4) => 2
(sqrt 2) => 1.4142135623730951
(sqrt -1) an error shall be signaled

*pi* → <float> named constant

The value of this constant is an approximation of π.

Example:

*pi* => 3.141592653589793

(sin x) → <number> function
(cos x) → <number> function
(tan x) → <number> function

The function sin returns the sine of x. The function cos returns the cosine of x. The function tan returns the tangent of x. In each case, x must be given in radians.

An error shall be signaled if x is not a number (error-id: domain-error).

Example:

;; Note that conforming processors are permitted to vary
;; in the floating precision of these results.
(sin 1) => 0.8414709848078965
(sin 0) => 0 or 0.0 (implementation-defined)
(sin 0.001) => 9.999999333333417E-4
(cos 1) => 0.5403023058681398
(cos 0) => 1 or 1.0 (implementation-defined)
(cos 0.001) => 0.99999950000000417
(tan 1) => 1.557407724654902
(tan 0) => 0 or 0.0 (implementation-defined)
(tan 0.001) => 0.0010000000333334668
(atan $x \rightarrow <number>$) \hspace{1cm} \textbf{function}

Returns the arc tangent of $x$.

The result is a (real) number that lies between $-\pi/2$ and $\pi/2$ (both exclusive).

The following definition for (one-argument) arc tangent determines the range and branch cuts:

$$\text{arctan } x = \frac{\log (1 + ix) - \log (1 - ix)}{2i}$$

An error shall be signaled if $x$ is not a number (error-id. \textit{domain-error}).

(atan2 $x_1 \ x_2 \rightarrow <number>$) \hspace{1cm} \textbf{function}

Given a point $(x_2, x_1)$ in rectangular coordinates, this function returns the phase of its representation in polar coordinates. If $x_1$ is zero and $x_2$ is negative, the result is positive. If $x_1$ and $x_2$ are both zero, the result is implementation defined.

An error shall be signaled if $x$ is not a number (error-id. \textit{domain-error}).

The value of \texttt{atan2} is always between $-\pi$ (exclusive) and $\pi$ (inclusive) when minus zero is not supported; when minus zero is supported, the range includes $-\pi$.

The signs of $x_1$ (indicated as $y$) and $x_2$ (indicated as $x$) are used to derive quadrant information. Figure 19.1 details various special cases. The asterisk (*) indicates that the entry in the figure applies to implementations that support minus zero.

\textbf{Example:}
\[(\text{atan2} \ 0 \ 3.0) \Rightarrow 0 \text{ or } 0.0 \quad (\text{implementation-defined})\]
\[(\text{atan2} \ 1 \ 1) \Rightarrow 0.7853981633974483\]
\[(\text{atan2} \ 1.0 \ -0.3) \Rightarrow 1.8622531212727635\]
\[(\text{atan2} \ 0.0 \ -0.5) \Rightarrow 3.141592653589793\]
\[(\text{atan2} \ -1 \ -1) \Rightarrow -2.356194490192345\]
\[(\text{atan2} \ -1.0 \ 0.3) \Rightarrow -1.2793396\]
\[(\text{atan2} \ 0.0 \ 0.5) \Rightarrow 0.0\]

\[\text{(defun asin} \ (x) \ (\text{atan2} \ x \ (\sqrt \ (-1 \ (\text{expt} \ x \ 2)))))) \Rightarrow \text{asin}\]
\[\text{(defun acos} \ (x) \ (\text{atan2} \ (\sqrt \ (-1 \ (\text{expt} \ x \ 2))) \ x)) \Rightarrow \text{acos}\]
\[\text{(defun atan} \ (x) \ (\text{atan2} \ x \ 1)) \Rightarrow \text{atan}\]

\[
\begin{align*}
\text{(sinh} \ x) & \rightarrow \langle\text{number}\rangle \quad \text{function} \\
\text{(cosh} \ x) & \rightarrow \langle\text{number}\rangle \quad \text{function} \\
\text{(tanh} \ x) & \rightarrow \langle\text{number}\rangle \quad \text{function}
\end{align*}
\]

The function \(\text{sinh}\) returns the hyperbolic sine of \(x\). The function \(\text{cosh}\) returns the hyperbolic cosine of \(x\). The function \(\text{tanh}\) returns the hyperbolic tangent of \(x\).

An error shall be signaled if \(x\) is not a number (error-id. \text{domain-error}).

**Example:**

\[
\begin{align*}
\text{(sinh} \ 1) & \Rightarrow 1.1752011936438014 \\
\text{(sinh} \ 0) & \Rightarrow 0 \text{ or } 0.0 \quad (\text{implementation-defined}) \\
\text{(sinh} \ 0.001) & \Rightarrow 0.001000000166666675 \\
\text{(cosh} \ 1) & \Rightarrow 1.5430806348152437 \\
\text{(cosh} \ 0) & \Rightarrow 1 \text{ or } 1.0 \quad (\text{implementation-defined}) \\
\text{(cosh} \ 0.001) & \Rightarrow 1.00000000000000416 \\
\text{(tanh} \ 1) & \Rightarrow 0.7615941559557649 \\
\text{(tanh} \ 0) & \Rightarrow 0 \text{ or } 0.0 \quad (\text{implementation-defined}) \\
\text{(tanh} \ 0.001) & \Rightarrow 9.999996666668002E-4
\end{align*}
\]

\[
\text{(atanh} \ x) \rightarrow \langle\text{number}\rangle \quad \text{function}
\]

Returns the hyperbolic arc tangent of \(x\). An error shall be signaled if \(x\) is not a number with absolute value less than 1 (error-id. \text{domain-error}).

**Example:**

\[
\begin{align*}
\text{(atanh} \ 0.5) & \Rightarrow 0.5493061443340549 \\
\text{(atanh} \ 0) & \Rightarrow 0 \text{ or } 0.0 \quad (\text{implementation-defined}) \\
\text{(atanh} \ 0.001) & \Rightarrow 0.00100000033333335
\end{align*}
\]

PUBLIC DOMAIN
(defun asinh (x)) (atanh (quotient x (sqrt (+ 1 (expt x 2))))) ⇒ asinh

(defun acosh (x)) (atanh (quotient (sqrt (* (- x 1) (+ x 1))) x))) ⇒ acosh

19.2 Float class

This class represents the set of floating-point numbers. Each floating-point number is represented by a rational number with some given precision; see IEEE standard 754-1985 for details.

Floating-point numbers are written in one of the following formats:

\[ s \cdot d . d \ldots d \]
\[ s \cdot d . d . d \ldots dE[s]d . d \ldots d \]
\[ s \cdot d . d . d . d[E][s]d . d \ldots d \]
\[ s \cdot d . d . d . d[E][s]d . d \ldots d \]

where \( s \) is either “+” or “-”, and \( d \ldots d \) is at least one digit from “0”-“9”.

There must be at least one digit before the decimal point and at least one mantissa digit after the decimal point.

---

*most-positive-float*  \(⇒ \langle\text{float}\rangle\)  named constant

*most-negative-float*  \(⇒ \langle\text{float}\rangle\)  named constant

---

The value of *most-positive-float* is the implementation-dependent floating-point number closest to positive infinity.

The value of *most-negative-float* is the implementation-dependent floating-point number closest to negative infinity.

---

(floatp obj)  \(⇒ \text{boolean}\)  function

Returns \( t \) if \( \text{obj} \) is a float (instance of class \( \langle\text{float}\rangle\)); otherwise, returns \( \text{nil} \). The \( \text{obj} \) may be any ISLISP object.

Example:

(floatp "2.4")  \(⇒ \text{nil}\)

(floatp 2)  \(⇒ \text{nil}\)

(floatp 2.0)  \(⇒ \text{t}\)

---

(float x)  \(⇒ \langle\text{float}\rangle\)  function

PUBLIC DOMAIN 77
Returns \( x \) itself if it is an instance of the class \(<\text{float}>\) and returns a floating-point approximation of \( x \) otherwise. An error shall be signaled if \( x \) is not a number (error-id. \textit{domain-error}).

\textbf{Example:}

\begin{align*}
(float \ 0) & \Rightarrow 0.0 \\
(float \ 2) & \Rightarrow 2.0 \\
(float \ -2.0) & \Rightarrow -2.0 \\
(float \ 123456789123456789123456789) & \Rightarrow 1.2345678912345679E26
\end{align*}

\textbf{(floor \( x \)) \rightarrow <\text{integer}>\hspace{1cm} function}

Returns the greatest integer less than or equal to \( x \). That is, \( x \) is truncated towards negative infinity. An error shall be signaled if \( x \) is not a number (error-id. \textit{domain-error}).

\textbf{Example:}

\begin{align*}
(floor \ 3.0) & \Rightarrow 3 \\
(floor \ 3.4) & \Rightarrow 3 \\
(floor \ 3.9) & \Rightarrow 3 \\
(floor \ -3.9) & \Rightarrow -4 \\
(floor \ -3.4) & \Rightarrow -4 \\
(floor \ -3.0) & \Rightarrow -3
\end{align*}

\textbf{(ceiling \( x \)) \rightarrow <\text{integer}>\hspace{1cm} function}

Returns the smallest integer that is not smaller than \( x \). That is, \( x \) is truncated towards positive infinity. An error shall be signaled if \( x \) is not a number (error-id. \textit{domain-error}).

\textbf{Example:}

\begin{align*}
(ceiling \ 3.0) & \Rightarrow 3 \\
(ceiling \ 3.4) & \Rightarrow 4 \\
(ceiling \ 3.9) & \Rightarrow 4 \\
(ceiling \ -3.9) & \Rightarrow -3 \\
(ceiling \ -3.4) & \Rightarrow -3 \\
(ceiling \ -3.0) & \Rightarrow -3
\end{align*}

\textbf{(truncate \( x \)) \rightarrow <\text{integer}>\hspace{1cm} function}
Returns the integer between 0 and x (inclusive) that is nearest to x. That is, x is truncated towards zero. An error shall be signaled if x is not a number (error-id. domain-error).

Example:

```
(truncate 3.0)  ⇒ 3
(truncate 3.4)  ⇒ 3
(truncate 3.9)  ⇒ 3
(truncate -3.4) ⇒ -3
(truncate -3.9) ⇒ -3
(truncate -3.0) ⇒ -3
```

```
(round x) → <integer>  function
```

Returns the integer nearest to x. If x is exactly halfway between two integers, the even one is chosen. An error shall be signaled if x is not a number (error-id. domain-error).

Example:

```
(round 3.0)  ⇒ 3
(round 3.4)  ⇒ 3
(round -3.4) ⇒ -3
(round 3.6)  ⇒ 4
(round -3.6) ⇒ -4
(round 3.5)  ⇒ 4
(round -3.5) ⇒ -4
(round 2.5)  ⇒ 2
(round -0.5) ⇒ 0
```

19.3 Integer class

Integer objects correspond to mathematical integers.

Arithmetic operations that only involve integers behave in a mathematically correct way, regardless of the size of the integer. If there are cases where arithmetic on integers would produce results or intermediate expressions that exceed the precision of the underlying hardware, an ISLISP processor shall simulate any necessary operations in software in order to assure mathematical correctness. The circumstances, if any, for which such simulation is necessary is implementation defined; the point at which such simulation will exceed the capacity of the processor is also implementation defined.

Integers are written in one of the following formats.

- `#B [s]b...b`, each b being either “0” or “1”.
- `#b [s]b...b`, each b being either “0” or “1”.

PUBLIC DOMAIN
\#0 \[s]oo...o, each \( o \) being one of \( \text{"0"-"7"} \).
\#o \[s]oo...o, each \( o \) being one of \( \text{"0"-"7"} \).
\[s]dd...d, each \( d \) being one of \( \text{"0"-"9"} \).
\#x \[s]xx...x, each \( x \) being one of \( \text{"0"-"9"} \), \( \text{"A"-"F"} \), \( \text{"A"-"F"} \).
\#x \[s]xx...x, each \( x \) being one of \( \text{"0"-"9"} \), \( \text{"A"-"F"} \), \( \text{"A"-"F"} \).

where \( s \) is either \( \text{"*"} \) or \( \text{"-"} \).

**Note:** In ISLISP, there is no variable that controls the reader. Thus the above notations are exactly the notations for integers.

\[
\text{(integerp \( \text{obj} \)) \rightarrow boolean} \hspace{2cm} \text{function}
\]

Returns \( t \) if \( \text{obj} \) is an integer (instance of class \(<\text{integer}>\)); otherwise, returns \( \text{nil} \). \( \text{obj} \) may be any ISLISP object.

**Example:**

\[
\begin{align*}
\text{(integerp 3)} & \Rightarrow t \\
\text{(integerp 3.4)} & \Rightarrow \text{nil} \\
\text{(integerp "4")} & \Rightarrow \text{nil} \\
\text{(integerp '(a b c))} & \Rightarrow \text{nil}
\end{align*}
\]

\[
\text{(div \( z_1 \), \( z_2 \)) \rightarrow <\text{integer}>} \hspace{2cm} \text{function}
\]
\[
\text{(mod \( z_1 \), \( z_2 \)) \rightarrow <\text{integer}>} \hspace{2cm} \text{function}
\]

\( \text{div} \) returns the greatest integer less than or equal to the quotient of \( z_1 \) and \( z_2 \). An error shall be signaled if \( z_2 \) is zero (error-id. \( \text{division-by-zero} \)).

\( \text{mod} \) returns the remainder of the integer division of \( z_1 \) by \( z_2 \). The sign of the result is the sign of \( z_2 \). The result lies between 0 (inclusive) and \( z_2 \) (exclusive), and the difference of \( z_1 \) and this result is divisible by \( z_2 \) without remainder.

\( \text{div} \) and \( \text{mod} \) satisfy:

\[
(= z_1 (+ (* (\text{div} z_1 z_2) z_2) (\text{mod} z_1 z_2)))
\]

That is, the evaluation of the above form always return \( t \).

An error shall be signaled if either \( z_1 \) or \( z_2 \) is not an integer (error-id. \( \text{domain-error} \)).

**Example:**

\[
\begin{align*}
\text{(div 12 3)} & \Rightarrow 4 \\
\text{(div 14 3)} & \Rightarrow 4 \\
\text{(div -12 3)} & \Rightarrow -4
\end{align*}
\]
\[ \text{(div -14 3)} \Rightarrow -5 \]
\[ \text{(div 12 -3)} \Rightarrow -4 \]
\[ \text{(div 14 -3)} \Rightarrow -5 \]
\[ \text{(div -12 -3)} \Rightarrow 4 \]
\[ \text{(div -14 -3)} \Rightarrow 4 \]
\[ \text{(mod 12 3)} \Rightarrow 0 \]
\[ \text{(mod 7 247)} \Rightarrow 7 \]
\[ \text{(mod 247 7)} \Rightarrow 2 \]
\[ \text{(mod 14 3)} \Rightarrow 2 \]
\[ \text{(mod -12 3)} \Rightarrow 0 \]
\[ \text{(mod -14 3)} \Rightarrow 1 \]
\[ \text{(mod 12 -3)} \Rightarrow 0 \]
\[ \text{(mod 14 -3)} \Rightarrow -1 \]
\[ \text{(mod -12 -3)} \Rightarrow 0 \]
\[ \text{(mod -14 -3)} \Rightarrow -2 \]

**function**

\[ (\text{gcd } z_1 \ z_2) \rightarrow <\text{integer}> \]

gcd returns the greatest common divisor of its integer arguments. The result is a non-negative integer. For nonzero arguments the greatest common divisor is the largest integer \( z \) such that \( z_1 \) and \( z_2 \) are integral multiples of \( z \).

An error shall be signaled if either \( z_1 \) or \( z_2 \) is not an integer (error-id. domain-error).

**Example:**

\[ (\text{gcd 12 5}) \Rightarrow 1 \]
\[ (\text{gcd 15 24}) \Rightarrow 3 \]
\[ (\text{gcd -15 24}) \Rightarrow 3 \]
\[ (\text{gcd 15 -24}) \Rightarrow 3 \]
\[ (\text{gcd -15 -24}) \Rightarrow 3 \]
\[ (\text{gcd 0 -4}) \Rightarrow 4 \]
\[ (\text{gcd 0 0}) \Rightarrow 0 \]

**function**

\[ (\text{lcm } z_1 \ z_2) \rightarrow <\text{integer}> \]

lcm returns the least common multiple of its integer arguments. gcd and lcm satisfies:

\[ (= (* (\text{gcd } m \ n) (\text{lcm } m \ n)) (\text{abs} (* m n))) \]

That is, the evaluation of the above form always return t.

An error shall be signaled if either \( z_1 \) or \( z_2 \) is not an integer (error-id. domain-error).

**Example:**

PUBLIC DOMAIN
ISLISP Working Draft 22.0

(lcm 2 3)  \Rightarrow  6
(lcm 15 24)  \Rightarrow  120
(lcm 15 -24)  \Rightarrow  120
(lcm -15 24)  \Rightarrow  120
(lcm -15 -24)  \Rightarrow  120
(lcm 0 -4)  \Rightarrow  0
(lcm 0 0)  \Rightarrow  0

(isqrt z)  \rightarrow  <integer>  \quad \text{function}

Returns the greatest integer less than or equal to the exact positive square root of z. An error shall be signaled if z is not a non-negative integer (error-id. domain-error).

Example:

(isqrt 49)  \Rightarrow  7
(isqrt 63)  \Rightarrow  7
(isqrt 100000000000000000000000000000000000000000000)
  \Rightarrow  100000000000000000

20 Character class

Characters are represented as instances of the <character> class. This insulates the programmer from particular character codes.

The ISLISP character set has at least ninety-five printing characters plus a newline character. The ISLISP printing characters are the space character, and the following ninety-four non-blank characters:

`! # $ % & ' ( ) * + . / 0 1 2 3 4 5 6 7 8 9 : ; < = > ? @ ABCDEFGHIJKLMNOPQRSTUVWXYZ [ \ ] ^ _ a b c d e f g h i j k l m n o p q r s t u v w x y z [ ] ^ _`

A character literal is denoted by #\ followed by a token which is either the character itself, or, if the character has a name, the character’s name. For example, the letter A is denoted by “#\A”. The newline and space characters have the names “newline” and “space,” respectively, so they can be denoted by “#\newline” and “#\space”. (Case is not significant when naming a character.)

Characters are ordered by char<, and this order satisfies:

```
0<1<2<3<4<5<6<7<8<9
&<#<$<%<<&'<( )*+./0123456789:;<>?@ABCDEFGHIJKLMNOPQRSTUVWXYZ[
\]^_abcdefghijklmnopqrstuvwxyz[ ]^_`
```

where char1 < char2 means that (char< char1 char2) is true.
(characterp obj) → boolean

Returns t if obj is a character (instance of class <character>); otherwise, returns nil. obj may be any ISLISP object.

Example:

(characterp "\a") ⇒ t
(characterp "a") ⇒ nil
(characterp 'a) ⇒ nil

(char= char1 char2) → boolean
(char/= char1 char2) → boolean
(char< char1 char2) → boolean
(char> char1 char2) → boolean
(char <= char1 char2) → boolean
(char >= char1 char2) → boolean

The function char= tests whether char1 is the same character as char2. The function char< tests whether char1 is less than char2. The function char <= tests whether char1 is less than or equal to char2. The ordering used is the partial order defined above, extended to a total order on all characters in an implementation-defined manner. If the test is satisfied, t is returned; otherwise, nil is returned.

Two characters are char=/= if and only if they are not char=. Two characters are char> if and only if they are not char<. Two characters are char>= if and only if they are not char<.

An error shall be signaled if either char1 or char2 is not a character (error-id. domain-error).

Example:

(char= #\a #\a) ⇒ t
(char= #\a #\b) ⇒ nil
(char= #\a #\A) ⇒ nil
(char/= #\a #\a) ⇒ nil
(char< #\a #\a) ⇒ nil
(char< #\a #\b) ⇒ t
(char< #\b #\a) ⇒ nil
(char< #\a #\A) ⇒ nil or t (implementation-defined)
(char< #\* #\a) ⇒ nil or t (implementation-defined)
(char> #\b #\a) ⇒ t
(char> #\a #\a) ⇒ t
(char<= #\a #\A) ⇒ nil or t (implementation-defined)
(char>= #\b #\a) ⇒ t
(char>= #\a #\a) ⇒ t
21  List class

The <list> class is partitioned into two subclasses <cons> and <null>.

21.1 Cons

A cons (sometimes also called “dotted pair”) consists of two components; the left component is
called car and the right component is called cdr. The constructor of this class is cons. Conses
are written as

(car . cdr)

where car and cdr denote the values in the car and cdr components, respectively, of the cons
object. As a special case, if the cdr value is nil, then the cons object is written as

(car)

Thus, in general, a data structure that consists of cons objects will be written in either of the
following formats:

(x_1 . (x_2 . . . (x_{n-1} . x_n) . . .))
(x_1 . (x_2 . . . (x_{n-1}) . . .))

These may be written, respectively, as

(x_1 x_2 . . . x_{n-1} . x_n)
(x_1 x_2 . . . x_{n-1})

(cons obj) \rightarrow boolean function

Returns t if obj is a cons (instance of class <cons>); otherwise, returns nil. obj may be any
ISLISP object.

Example:

(cons '(a . b)) \Rightarrow t
(cons '(a b c)) \Rightarrow t
(cons '()) \Rightarrow nil
(cons #(a b)) \Rightarrow nil

(cons obj1 obj2) \rightarrow <cons> function
This function builds a cons from two objects, with \texttt{obj}_1 as its car (or 'left') part and with \texttt{obj}_2 as its cdr (or 'right') part. An error shall be signaled if the requested cons cannot be allocated (error-id. \textit{cannot-create-cons}). Both \texttt{obj}_1 and \texttt{obj}_2 may be any ISLISP object.

\textbf{Example:}

\begin{verbatim}
(cons 'a ())    \Rightarrow (a)
(cons '(a) '(b c d)) \Rightarrow ((a) b c d)
(cons "a" '(b c)) \Rightarrow ("a" b c)
(cons 'a 3) \Rightarrow (a . 3)
(cons '(a b) 'c) \Rightarrow ((a b) . c)
\end{verbatim}

\textbf{function}\n
\begin{verbatim}
(car cons) \rightarrow <object>
\end{verbatim}

The function \texttt{car} returns the left component of the cons. An error shall be signaled if \texttt{cons} is not a cons (error-id. \textit{domain-error}).

\textbf{Example:}

\begin{verbatim}
(car '()) \hspace{1cm} an error shall be signaled
(car '(a b c)) \Rightarrow a
(car '((a) b c d)) \Rightarrow (a)
(car '(1 . 2)) \Rightarrow 1
\end{verbatim}

\textbf{function}\n
\begin{verbatim}
(cdr cons) \rightarrow <object>
\end{verbatim}

The function \texttt{cdr} returns the right component of the cons. An error shall be signaled if \texttt{cons} is not a cons (error-id. \textit{domain-error}).

\textbf{Example:}

\begin{verbatim}
(cdr '()) \hspace{1cm} an error shall be signaled
(cdr '((a) b c d)) \Rightarrow (b c d)
(cdr '(1 . 2)) \Rightarrow 2
\end{verbatim}

\textbf{special form}\n
\textbf{function}\n
\begin{verbatim}
(setf (car cons) obj) \rightarrow <object>
(set-car obj cons) \rightarrow <object>
\end{verbatim}

Updates the left component of \texttt{cons} with \texttt{obj}. The returned value is \texttt{obj}. An error shall be signaled if \texttt{cons} is not a cons (error-id. \textit{domain-error}). \texttt{obj} may be any ISLISP object.
Example:

\[
\begin{aligned}
\text{(let ((x (list 'apple 'orange)))} \\
\text{  (list x (car x))} \\
\text{  (setf (car x) 'banana)} \\
\text{  x (car x))}) \\
\Rightarrow ((\text{banana} \text{ orange}) \text{ apple} \text{ banana} (\text{banana} \text{ orange}) \text{ banana})
\end{aligned}
\]

\[
\begin{array}{ll}
\text{(setf (cdr cons) obj) } & \rightarrow <\text{object}> & \text{special form} \\
\text{(set-cdr obj cons) } & \rightarrow <\text{object}> & \text{function}
\end{array}
\]

Updates the right component of \text{cons} with \text{obj}. The returned value is \text{obj}. An error shall be signaled if \text{cons} is not a cons (error-id. \text{domain-error}). \text{obj} may be any \text{ISLISP} object.

Example:

\[
\begin{aligned}
\text{(let ((x (list 'apple 'orange)))} \\
\text{  (list x (cdr x))} \\
\text{  (setf (cdr x) 'banana)} \\
\text{  x (cdr x))}) \\
\Rightarrow ((\text{apple} . \text{banana}) (\text{orange}) \text{ banana} (\text{apple} . \text{banana}) \text{ banana})
\end{aligned}
\]

21.2 Null class

This class consists of only one element, the object called \text{nil}. This object is the false value in boolean expressions. The length of the sequence \text{nil} is 0.

\[
\begin{array}{ll}
\text{(null obj) } & \rightarrow \text{boolean} & \text{function}
\end{array}
\]

Returns t if \text{obj} is \text{nil}; otherwise, returns \text{nil}.\textsuperscript{5} \text{obj} may be any \text{ISLISP} object.

Example:

\[
\begin{aligned}
\text{(null '(a b c))} & \Rightarrow \text{nil} \\
\text{(null '())} & \Rightarrow \text{t} \\
\text{(null (list))} & \Rightarrow \text{t}
\end{aligned}
\]

21.3 List operations

\textsuperscript{5}If the naming conventions were strictly observed, \text{null} would be named \text{nullisp}; it is named \text{null} for historical and compatibility reasons.
(listp obj) → boolean  

function

Returns t if obj is a list (instance of class list); otherwise, returns nil. obj may be any ISLISP object.

Example:

(listp '(a b c))  ⇒  t
(listp '())      ⇒  t
(listp '(a . b))  ⇒  t
(let ((x (list 'a)))
  (setf (cdr x) x))  ⇒  t
(listp "abc")    ⇒  nil
(listp '(1 2))   ⇒  nil
(listp 'jerome)  ⇒  nil

(create-list i [initial-element]) → <list>  

function

Returns a list of length i. If initial-element is given, the elements of the new list are initialized with this object; otherwise, the initialization is implementation defined. An error shall be signaled if the requested list cannot be allocated (error-id: cannot-create-list). An error shall be signaled if i is not a non-negative integer (error-id: domain-error). initial-element may be any ISLISP object.

Example:

(create-list 3 '17)      ⇒  (17 17 17)
(create-list 2 '#a)      ⇒  ('#a '#a)

(list obj*) → <list>

function

Returns a new list whose length is the number of arguments and whose elements are the arguments in the same order as in the list-form. An error shall be signaled if the requested list cannot be allocated (error-id: cannot-create-list). Each obj may be any ISLISP object.

Example:

(list 'a (+ 3 4) 'c)  ⇒  (a 7 c)
(list)              ⇒  nil
(reverse list) \rightarrow <list> \quad \text{function}

(nreverse list) \rightarrow <list> \quad \text{function}

These functions each return a list whose elements are those of the given list, but in reverse order. An error shall be signaled if list is not a list (error-id. domain-error).

For reverse, no side-effect to the given list occurs. The resulting list is permitted but not required to share structure with the input list.

For nreverse, the conses which make up the top level of the given list are permitted, but not required, to be side-effected in order to produce this new list. nreverse should never be called on a literal object.

Example:

(reverse '(a b c d e)) \Rightarrow (e d c b a)
(reverse '(a)) \Rightarrow (a)
(reverse '()) \Rightarrow ()
(let* ((x (list 'a 'b)) (y (nreverse x))) (equal x y))
\Rightarrow \text{implementation-defined}

(append list*) \rightarrow <list> \quad \text{function}

Returns the result of appending all of the lists, or () if given no lists. An error shall be signaled if any list is not a list (error-id. domain-error).

This function does not modify its arguments. It is implementation defined whether and when the result shares structure with its list arguments.

An error shall be signaled if the list cannot be allocated (error-id. cannot-create-list).

Example:

(append '(a b c) '(d e f)) \Rightarrow (a b c d e f)

(member obj list) \rightarrow <list> \quad \text{function}

If list contains at least one occurrence of obj (as determined by eq1), the first sublist of list whose car is obj is returned. Otherwise, nil is returned. An error shall be signaled if list is not a list (error-id. domain-error).

Example:

(member 'c '(a b c d e f)) \Rightarrow (c d e f)
(member 'g '(a b c d e f))  ⇒ nil
(member 'c '(a b c a b c))  ⇒ (c a b c)

(mapcar function list+)  → <list>
(mapc function list+)  → <list>
(mapcan function list+)  → <list>
(maplist function list+)  → <list>
(mapl function list+)  → <list>
(mapcon function list+)  → <list>

Successively applies the given function to sets of arguments determined by the given lists. The way in which the arguments are determined, and the way in which the result is accumulated are how these functions differ.

<table>
<thead>
<tr>
<th>Function</th>
<th>Argument</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>mapcar</td>
<td>successive elements</td>
<td>successive cons</td>
</tr>
<tr>
<td>mapc</td>
<td>successive elements</td>
<td>none (i.e., \text{list}_1) returned</td>
</tr>
<tr>
<td>mapcan</td>
<td>successive elements</td>
<td>successive “destructive append”</td>
</tr>
<tr>
<td>maplist</td>
<td>successive sublists</td>
<td>successive cons</td>
</tr>
<tr>
<td>mapl</td>
<td>successive sublists</td>
<td>none (i.e., \text{list}_1) returned</td>
</tr>
<tr>
<td>mapcon</td>
<td>successive sublists</td>
<td>successive “destructive append”</td>
</tr>
</tbody>
</table>

mapcar operates on successive elements of the lists. function is applied to the first element of each list, then to the second element of each list, and so on. The iteration terminates when the shortest list runs out, and excess elements in other lists are ignored. The value returned by mapcar is a list of the results of successive calls to function.

mapc is like mapcar except that the results of applying function are not accumulated; list1 is returned.

maplist is like mapcar except that function is applied to successive sublists of the lists. function is first applied to the lists themselves, and then to the cdr of each list, and then to the cdr of the cdr of each list, and so on.

mapl is like maplist except that the results of applying function are not accumulated; list1 is returned.

mapcan and mapcon are like mapcar and maplist respectively, except that the results of applying function are combined into a list by the use of an operation that performs a destructive form of append rather than list.

An error shall be signaled if function is not a function (error-id. domain-error). An error shall be signaled if any list is not a list (error-id. domain-error).

In all cases, the calls to function proceed from left to right, so that if function has side effects, it can rely upon being called first on all of the elements with index 0, then on all of those numbered 1, and so on.

Example:
(mapcar #\'car '((1 a) (2 b) (3 c)))  ⇒ (1 2 3)
(mapcar #\'abs '(3 -4 2 -5 -6))  ⇒ (3 4 2 5 6)
(mapcar #\'cons '(a b c) '(1 2 3))  ⇒ ((a . 1) (b . 2) (c . 3))

(let ((x 0)) (mapc (lambda (v) (setq x (+ x v))) '(3 5)) x)
  ⇒ 8

(maplist #\'append '(1 2 3 4) '(1 2) '(1 2 3))
  ⇒ ((1 2 3 4 1 2 1 2 3) (2 3 4 2 2 3))
(maplist (lambda (x) (cons 'foo x)) '(a b c d))
  ⇒ ((foo a b c d) (foo b c d) (foo c d) (foo d))
(maplist (lambda (x) (if (member (car x) (cdr x)) 0 1))
  '(a b a c d b b c))
  ⇒ (0 0 1 0 1 1 1)

(let ((k 0))
  (mapl (lambda (x)
            (setq k (+ k (if (member (car x) (cdr x)) 0 1))))
            k))
  ⇒ 4

(mapcan (lambda (x) (if (> x 0) (list x))) '(-3 4 0 5 -2 7))
  ⇒ (4 5 7)

(mapcon (lambda (x) (if (member (car x) (cdr x)) (list (car x)))
           (a b a c d b c b))
   ⇒ (a b c b c)

(mapcon #\'list '(1 2 3 4))  ⇒ ((1 2 3 4) (2 3 4) (3 4) (4))

(assoc obj association-list)  ⇒ <list>

If association-list contains at least one cons whose car is obj (as determined by eqv), the first such cons is returned. Otherwise, nil is returned. An error shall be signaled if association-list is not a list of conses (error-id: domain-error).

Example:

(assoc 'a '((a . 1) (b . 2)))  ⇒ (a . 1)
(assoc 'a '((a . 1) (a . 2)))  ⇒ (a . 1)
(assoc 'c '((a . 1) (b . 2)))  ⇒ nil
22 Arrays

22.1 Array classes

Arrays store data in array components, which are indexed by a tuple of non-negative integers called indices.

The total number of elements in the array is the product of the dimensions. Zero-dimensional arrays are permissible and, as a consequence of this rule, can store exactly one element, indexed by an empty tuple of indices.

There are several array classes. For a pictorial representation of their inheritance relationship, see Figure 1. The following is an explanation of the purpose of each of these classes:

- `<basic-array>`
  All arrays are of the abstract class `<basic-array>`, but (as with all abstract classes) there are no direct instances of this class. It is provided for type discrimination purposes only.
  ISLISP defines two direct subclasses of `<basic-array>`: `<basic-vector>` and `<basic-array*>`. These classes are mutually exclusive and form an exhaustive partition of the set of basic-arrays. There shall be no other direct subclasses of `<basic-array>`.

- `<basic-vector>`
  All one-dimensional arrays are of the abstract class `<basic-vector>`, but (as with all abstract classes) there are no direct instances of this class. It is provided for type discrimination purposes only.
  ISLISP defines only two direct subclasses of `<basic-vector>`: `<general-vector>` and `<string>`. There may be additional, implementation-defined subclasses of `<basic-vector>`.
  Note: An implementation might provide specialized array representations for one-dimensional arrays of bits. If provided, such an array representation would be subclass of `<basic-vector>`.

- `<general-vector>`
  An object of class `<general-vector>` is a one-dimensional array that is capable of holding elements of type `<object>`. When the function `<create-array>` is asked to create a one-dimensional array, the resulting array is of this class.

- `<string>`
  An object of class `<string>` is a one-dimensional array that is capable only of holding elements of type `<character>`. When the function `<create-string>` is used, the result is of this class.

- `<basic-array*>`
  All non-one-dimensional arrays are of the abstract class `<basic-array*>`, but (as with all abstract classes) there are no direct instances of this class. It is provided for type discrimination purposes only.
  ISLISP defines only one direct subclass of `<basic-array*>`: `<general-array*>`. There may be additional, implementation-defined subclasses of `<basic-array*>`.
  Note: An implementation might provide specialized array representations for two-dimensional arrays of 1 or more bits to hold display information for a monochrome or color screen. If provided, such array representations would be subclasses of `<basic-array*>`.
22.2 General arrays

An object that is either of class `<general-vector>` or of class `<general-array*>` is sometimes called a "general array."

General arrays are capable of storing any object of class `<object>`. Those arrays that are not general arrays are the ones restricted to storage objects of more specialized classes.

A general array can be expressed as a textual literal using `#n` notation (where `n` is an integer indicating the number of dimensions of the array) followed by a nested list of sequences denoting the contents of the array. This structure can be defined as follows. If `n = 1` the structure is simply `(obj1 ... objn)`. If `n > 1` and the dimensions are `(n1 n2 ... )`, the structure is `(str1 ... strn)`, where the `str` are the structures of the `n1` subarrays, each of which has dimensions `(n2 ... )`. For example, the textual representation of `(create-array '(2 3 4) 5)` is as follows: `#3a(((5 5 5) (5 5 5) (5 5 5)) ((5 5 5) (5 5 5) (5 5 5)))`.

22.3 Array operations

To manipulate arrays ISLISP provides the following functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>(basic-array-p obj)</code></td>
<td>→ boolean</td>
</tr>
<tr>
<td><code>(basic-array* p obj)</code></td>
<td>→ boolean</td>
</tr>
<tr>
<td><code>(general-array* p obj)</code></td>
<td>→ boolean</td>
</tr>
</tbody>
</table>

`basic-array-p` returns `t` if `obj` is a `basic-array` (instance of class `<basic-array*>`); otherwise, returns `nil`. `obj` may be any ISLISP object.

`basic-array*` returns `t` if `obj` is a `basic-array*` (instance of class `<basic-array*>`); otherwise, returns `nil`. `obj` may be any ISLISP object.

`general-array*` returns `t` if `obj` is a `general-array*` (instance of class `<general-array*>`); otherwise, returns `nil`. `obj` may be any ISLISP object.

Example:

```lisp
(mapcar (lambda (x)
  (list (basic-array-p x)
        (basic-array* p x)
        (general-array* p x)))
'((a b c)
 "abc"
 #(a b c))
```
\#1a(a b c)
\#2a((a) (b) (c)))
⇒ ((nil nil nil) (t nil nil) (t nil nil) (t t t))

<table>
<thead>
<tr>
<th>create-array dimensions [initial-element]</th>
<th>function</th>
</tr>
</thead>
<tbody>
<tr>
<td>This function creates an array of the given dimensions. The dimensions argument is a list of non-negative integers.</td>
<td></td>
</tr>
<tr>
<td>The result is of class <code>&lt;general-vector&gt;</code> if there is only one dimension, or of class <code>&lt;general-array*&gt;</code> otherwise.</td>
<td></td>
</tr>
<tr>
<td>If initial-element is given, the elements of the new array are initialized with this object, otherwise the initialization is implementation defined.</td>
<td></td>
</tr>
<tr>
<td>An error shall be signaled if the requested array cannot be allocated (error-id. <code>cannot-create-array</code>).</td>
<td></td>
</tr>
<tr>
<td>An error shall be signaled if dimensions is not a proper list of non-negative integers (error-id. <code>domain-error</code>). initial-element may be any ISLISP object.</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>(create-array '(2 3) 0.0) ⇒ #2a((0.0 0.0 0.0) (0.0 0.0 0.0))</td>
<td></td>
</tr>
<tr>
<td>(create-array *(2) 0.0) ⇒ #(0.0 0.0)</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>aref basic-array z*</th>
<th>function</th>
</tr>
</thead>
<tbody>
<tr>
<td>garef general-array z*</td>
<td>function</td>
</tr>
<tr>
<td>aref returns the object stored in the component of the basic-array specified by the sequence of integers z. This sequence must have exactly as many elements as there are dimensions in the basic-array, and each one must satisfy 0 ≤ z_i &lt; d_i the i\textsuperscript{th} dimension and 0 ≤ i &lt; d, d the number of dimensions. Arrays are indexed 0 based, so the i\textsuperscript{th} row is accessed via the index i - 1.</td>
<td></td>
</tr>
<tr>
<td>An error shall be signaled if basic-array is not a basic-array (error-id. <code>domain-error</code>). An error shall be signaled if any z is not a non-negative integer (error-id. <code>domain-error</code>).</td>
<td></td>
</tr>
<tr>
<td>garef is like aref but an error shall be signaled if its first argument, general-array, is not an object of class <code>&lt;general-vector&gt;</code> or of class <code>&lt;general-array*&gt;</code> (error-id. <code>domain-error</code>).</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>(defglobal array1 (create-array '(3 3 0)))</td>
<td></td>
</tr>
<tr>
<td>⇒ array1</td>
<td></td>
</tr>
<tr>
<td>array1</td>
<td></td>
</tr>
</tbody>
</table>

PUBLIC DOMAIN
ISLISP Working Draft 22.0

\[ \Rightarrow \#3a(((0 0 0) (0 0 0) (0 0 0))
((0 0 0) (0 0 0) (0 0 0))
((0 0 0) (0 0 0) (0 0 0))) \]

(aref array1 0 1 2) \Rightarrow 0
(setf (aref array1 0 1 2) 3.14) \Rightarrow 3.14
(aref array1 0 1 2) \Rightarrow 3.14

(aref (create-array '(8 8) 6 1 1) \Rightarrow 6
(aref (create-array '() 19)) \Rightarrow 19

(setf (aref basic-array z*) obj) \rightarrow <object> special form
(set-aref obj basic-array z*) \rightarrow <object> function
(setf (garef general-array z*) obj) \rightarrow <object> special form
(set-garef obj general-array z*) \rightarrow <object> function

These replace the object obtainable by aref or garef with obj. The returned value is obj. The constraints on the basic-array, the general-array, and the sequence of indices z is the same as for aref and garef.

Example:

(setf (aref array1 0 1 2) 3.15) \Rightarrow 3.15
(set-aref 51.3 array1 0 1 2) \Rightarrow 51.3

(array-dimensions basic-array) \rightarrow <list> function

Returns a list of the dimensions of a given basic-array. An error shall be signaled if basic-array is not a basic-array (error-id. domain-error). The consequences are undefined if the returned list is modified.

Example:

(array-dimensions (create-array '(2 2) 0)) \Rightarrow (2 2)
(array-dimensions (vector 'a 'b)) \Rightarrow (2)
(array-dimensions "foo") \Rightarrow (3)

23 Vectors

A vector is a one dimensional array. See §22.1 for detailed information about the relationship of arrays and vectors.
General vectors are written as follows:

\[(x_1 \ x_2 \ \ldots \ x_n)\]

(basic-vector-p obj) \rightarrow boolean
function

(general-vector-p obj) \rightarrow boolean
function

basic-vector-p returns t if obj is a basic-vector (instance of class \<basic-vector\>); otherwise, returns nil. obj may be any ISLISP object.

general-vector-p returns t if obj is a general-vector (instance of class \<general-vector\>); otherwise, returns nil. obj may be any ISLISP object.

Example:

(mapcar (lambda (x)
  (list (basic-vector-p x)
      (general-vector-p x)))
  '((a b c)
     "abc"
    #\(a\ b\ c\)
    #1a(a b c)
    #2a(a (b (c)))))
⇒ ((nil nil) (t nil) (t t) (t t) (nil nil))

(create-vector i [initial-element]) \rightarrow \<general-vector\>
function

Returns a general-vector of length i. If initial-element is given, the elements of the new vector are initialized with this object, otherwise the initialization is implementation defined. An error shall be signaled if the requested vector cannot be allocated (error-id. cannot-create-vector). An error shall be signaled if i is not a non-negative integer (error-id. domain-error). initial-element may be any ISLISP object.

Example:

(create-vector 3 17) ⇒ #(17 17 17)
(create-vector 2 #\a) ⇒ #\(\#\a \#\a\)

(vector obj*) \rightarrow \<general-vector\>
function

Returns a new general-vector whose elements are its obj arguments. The length of the newly created vector is, therefore, the number of obj is passed as arguments. The vector is indexed by integers ranging from 0 to dimension-1. An error shall be signaled if the requested vector cannot be allocated (error-id. cannot-create-vector). Each obj may be any ISLISP object.
24 String class

A string is a vector that is capable only of holding elements of type `<character>`. See §22.1 for detailed information about the relationship of arrays, vectors, and strings.

Any implementation-defined character can be a string element. In ISLISP, string indices are 0-based. Strings are written by listing all the element characters in order and by enclosing them with double quotes “"”. If the string has a double quote as its element, the double quote must be preceded by a backslash “\"”. If the string has a backslash as its element, the backslash must be preceded by another backslash. Strings contained in program text as literals are immutable objects. The representation of non-printing characters is implementation defined.

---

**Example:**

```
(vector 'a 'b 'c)       ⇒ #(a b c)
(vector)               ⇒ #()  
```

---

### (stringp obj) → boolean

**function**

Returns `t` if `obj` is a string (instance of class `<string>`); otherwise, returns `nil`. `obj` may be any ISLISP object.

**Example:**

```
(stringp "abc")         ⇒ t
(stringp 'abc)           ⇒ nil
```

---

### (create-string i [initial-character]) → <string>

**function**

Returns a string of length `i`. If `initial-character` is given, then the characters of the new string are initialized with this character, otherwise the initialization is implementation defined. An error shall be signaled if the requested string cannot be allocated (error-id: `cannot-create-string`). An error shall be signaled if `i` is not a non-negative integer or if `initial-character` is not a character (error-id: `domain-error`).

**Example:**

```
(create-string 3 #\a)   ⇒ "aaa"
(create-string 0 #\a)   ⇒ ""
```
(string= string1 string2) \rightarrow\text{quasi-boolean} \quad \text{function}

(string/= string1 string2) \rightarrow\text{quasi-boolean} \quad \text{function}

(string< string1 string2) \rightarrow\text{quasi-boolean} \quad \text{function}

(string> string1 string2) \rightarrow\text{quasi-boolean} \quad \text{function}

(string>= string1 string2) \rightarrow\text{quasi-boolean} \quad \text{function}

(string<= string1 string2) \rightarrow\text{quasi-boolean} \quad \text{function}

The function `string=` tests whether `string_1` is the same string as `string_2`. The function `string<` tests whether `string_1` is less than `string_2`. The function `string<=` tests whether `string_1` is less than or equal to `string_2`.

The ordering used is based on character comparisons.

Two strings are `string=` if they are of the same length, \( l \), and if for every \( i \), where \( 0 \leq i < l \), \((\text{char}\,=\,\text{elt}\,\text{string}_1\,i,\,\text{elt}\,\text{string}_2\,i)\) holds.

Two strings `string_1` and `string_2` are in order `string<` if in the first position in which they differ the character of `string_1` is `char<` the corresponding character of `string_2`, or if `string_1` is a proper prefix of `string_2` (of shorter length and matching in all the characters of `string_1`).

Two strings are `string<=` if they are either `string<` or they are `string=``.

Two strings are `string/=` if and only if they are not `string=`. Two strings are `string>` if and only if they are not `string<=`. Two strings are `string>=` if and only if they are not `string<`.

For these 6 string comparison functions, if the test is satisfied, an implementation-defined non-nil value is returned; otherwise, `nil` is returned.

An error shall be signaled if either `string_1` or `string_2` is not a string (error-id: `domain-error`).

Example:

```
(if (string= "abcd" "abcd") t nil) \Rightarrow t
(if (string= "abcd" "wxyz") t nil) \Rightarrow nil
(if (string= "abcde" "abcd") t nil) \Rightarrow nil
(if (string/= "abcd" "wxyz") t nil) \Rightarrow t
(if (string< "abc" "abcd") t nil) \Rightarrow nil
(if (string< "abc" "wxyz") t nil) \Rightarrow t
(if (string<= "abc" "abcd") t nil) \Rightarrow t
(if (string<= "abc" "wxyz") t nil) \Rightarrow t
(if (string<= "abcde" "abcd") t nil) \Rightarrow nil
(if (string> "abc" "wxyz") t nil) \Rightarrow nil
(if (string> "abcd" "abce") t nil) \Rightarrow t
```

(char-index char string [start-position]) \rightarrow <\text{object}> \quad \text{function}
ISLISP Working Draft 22.0

Returns the position of char in string. The search starts from the position indicated by start-position (which is 0-based and defaults to 0). The value returned if the search succeeds is an offset from the beginning of the string, not from the starting point. If the char does not occur in the string, nil is returned. The function char= is used for the comparisons.

An error shall be signaled if char is not a character or if string is not a string (error-id. domain-error).

Example:

(char-index #\b "abcab")  ⇒ 1
(char-index #\B "abcab")  ⇒ nil
(char-index #\b "abcab" 2)  ⇒ 4
(char-index #\d "abcab")  ⇒ nil
(char-index #\a "abcab" 4)  ⇒ nil

(string-index substring string [start-position])  →  <object>  function

Returns the position of the given substring within string. The search starts from the position indicated by start-position (which is 0-based and defaults to 0). The value returned if the search succeeds is an offset from the beginning of the string, not from the starting point. If that substring does not occur in the string, nil is returned. Presence of the substring is done by sequential use of char= on corresponding elements of the two strings.

An error shall be signaled if either substring or string is not a string (error-id. domain-error).

Example:

(string-index "foo" "foobar")  ⇒ 0
(string-index "bar" "foobar")  ⇒ 3
(string-index "FOO" "foobar")  ⇒ nil
(string-index "foo" "foobar" 1)  ⇒ nil
(string-index "bar" "foobar" 1)  ⇒ 3
(string-index "foo" "")  ⇒ nil
(string-index "foo" "foo")  ⇒ 0

(string-append string*)  →  <string>  function

Returns a single string containing a sequence of characters that results from appending the sequences of characters of each of the strings, or "" if given no strings. An error shall be signaled if any string is not a string (error-id. domain-error).

This function does not modify its arguments. It is implementation defined whether and when the result shares structure with its string arguments.

An error shall be signaled if the string cannot be allocated (error-id. cannot-create-string).

98  PUBLIC DOMAIN
25 Sequence functions

Objects that are either of class `<basic-vector>` or of class `<list>` are sometimes called "sequences". The operations upon sequences are called "sequence functions."

\[
\begin{align*}
\text{(length sequence)} & \rightarrow \langle \text{integer} \rangle \\
\end{align*}
\]

function

Returns the length of `sequence` as an integer greater than or equal to 0.

When `sequence` is a basic-vector, `length` returns its dimension.

When `sequence` is a list, the result is the number of elements in the list; if an element is itself a list, the elements within this sublist are not counted. In the case of dotted lists, `length` returns the number of conses at the uppermost level of the list. For example, \(\text{(length '(a b . c))} \Rightarrow 2\), since \(\text{(a b . c)} \equiv \text{(cons 'a (cons 'b 'c))}\).

An error shall be signaled if `sequence` is not a basic-vector or a list (error-id. `domain-error`).

Example:

\[
\begin{align*}
\text{(length '(a b c))} & \Rightarrow 3 \\
\text{(length '(a (b (c d e))))} & \Rightarrow 3 \\
\text{(length '())} & \Rightarrow 0 \\
\text{(length (vector 'a 'b 'c))} & \Rightarrow 3 \\
\end{align*}
\]

\[
\begin{align*}
\text{(elt sequence z)} & \rightarrow \langle \text{object} \rangle \\
\end{align*}
\]

function

Given a `sequence` and an integer `z` satisfying \(0 \leq z < \text{(length sequence)}\), `elt` returns the element of `sequence` that has index `z`. Indexing is 0-based; i.e., `z = 0` designates the first element. An error shall be signaled if `z` is an integer outside of the mentioned range (error-id. `index-out-of-range`).

An error shall be signaled if `sequence` is not a basic-vector or a list or if `z` is not an integer (error-id. `domain-error`).
Example:

\[
\begin{align*}
(\text{elt } '(a\ b\ c)\ 2) & \Rightarrow c \\
(\text{elt} \ (\text{vector } 'a\ 'b\ 'c)\ 1) & \Rightarrow b \\
(\text{elt} \ "abc"\ 0) & \Rightarrow \#\a
\end{align*}
\]

| (setf (elt sequence z) obj) → <object> | special form |
| (set-elt obj sequence z) → <object> | function |

These replace the object obtainable by elt with obj. The returned value is obj.

An error shall be signaled if \(z\) is an integer outside of the valid range of indices (error-id. \text{index-out-of-range}). An error shall be signaled if \text{sequence} is not a basic-vector or a list or if \(z\) is not an integer (error-id. \text{domain-error}). obj may be any ISLISP object.

Example:

\[
\begin{align*}
(\text{let} \ ((\text{string} \ (\text{create-string} \ 5 \ \#\x)))
  (\text{setf} \ (\text{elt} \ \text{string} \ 2) \ \#\0)
  \text{x}) & \Rightarrow "xx0xx"
\end{align*}
\]

| (subseq sequence \(z_1\ \ z_2\)) → sequence | function |

Given a sequence \text{sequence} and two integers \(z_1\) and \(z_2\) satisfying \(0 \leq z_1 \leq z_2 \leq (\text{length} \ \text{sequence})\), this function returns the subsequence of length \(z_2 - z_1\), containing the elements with indices from \(z_1\) (inclusive) to \(z_2\) (exclusive). The subsequence is newly allocated, and has the same class as \text{sequence}.

An error shall be signaled if the requested subsequence cannot be allocated (error-id. \text{cannot-create-sequence}). An error shall be signaled if \(z_1\) or \(z_2\) are outside of the bounds mentioned (error-id. \text{index-out-of-range}). An error shall be signaled if \text{sequence} is not a basic-vector or a list, or if \(z_1\) is not an integer, or if \(z_2\) is not an integer (error-id. \text{domain-error}.

Example:

\[
\begin{align*}
(\text{subseq} \ "abcdef"\ 1\ 4) & \Rightarrow "bcd" \\
(\text{subseq} \ '(a\ b\ c\ d\ e\ f)\ 1\ 4) & \Rightarrow (b\ c\ d) \\
(\text{subseq} \ (\text{vector} \ 'a\ 'b\ 'c\ 'd\ 'e\ 'f)\ 1\ 4) \\
  & \Rightarrow #(b\ c\ d)
\end{align*}
\]

| (map-into destination function sequence*) → sequence | function |

100   PUBLIC DOMAIN
Destructively modifies destination to contain the results of applying function to successive elements in the sequences. The destination is returned.

If destination and each element of sequences are not all the same length, the iteration terminates when the shortest sequence (of any of the sequences or the destination) is exhausted.

The calls to function proceed from left to right, so that if function has side effects, it can rely upon being called first on all of the elements with index 0, then on all of those numbered 1, and so on.

An error shall be signaled if destination is not a basic-vector or a list (error-id. domain-error). An error shall be signaled if any sequence is not a basic-vector or a list (error-id. domain-error).

Example:

```lisp
(setq a (list 1 2 3 4)) ⇒ (1 2 3 4)
(setq b (list 10 10 10 10)) ⇒ (10 10 10 10)
(map-into a #'+ a b) ⇒ (11 12 13 14)
a ⇒ (11 12 13 14)
b ⇒ (10 10 10 10)
(setq k '(one two three)) ⇒ (one two three)
(map-into a #'cons k a) ⇒ ((one . 11) (two . 12) (three . 13) 14)
(let ((x 0))
  (map-into a
    (lambda () (setq x (+ x 2)))))
⇒ (2 4 6 8)
a ⇒ (2 4 6 8)
```

### 26 Stream class

Streams are instances of the <stream> class. They are objects that serve as sources or sinks of data.

<table>
<thead>
<tr>
<th>(streamp obj)</th>
<th>→ boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>function</td>
<td></td>
</tr>
</tbody>
</table>

Returns t if obj is a stream (instance of class <stream>); otherwise, returns nil. obj may be any ISLISP object. streamp is unaffected by whether its argument, if an instance of the class <stream>, is open or closed.

Example:

```lisp
(streamp (standard-input)) ⇒ t
(streamp '()) ⇒ nil
```
ISLISP Working Draft 22.0

(open-stream-p obj) → boolean  
function

Returns t if obj is an open stream; otherwise, returns nil.

(input-stream-p obj) → boolean  
function

Returns t if obj is a stream that can handle input operations; otherwise, returns nil.

Example:

(input-stream-p (standard-input)) ⇒ t
(input-stream-p (standard-output)) ⇒ nil
(input-stream-p '(a b c)) ⇒ nil

(output-stream-p obj) → boolean  
function

Returns t if obj is a stream that can handle output operations; otherwise, returns nil.

Example:

(output-stream-p (standard-output)) ⇒ t
(output-stream-p (standard-input)) ⇒ nil
(output-stream-p "hello") ⇒ nil

(standard-input) → <stream>  
function

(standard-output) → <stream>  
function

(error-output) → <stream>  
function

The function standard-input returns the stream used as the default stream for input functions.

The function standard-output returns the stream used as the default stream for output functions.

The function error-output returns the stream used as the default stream for warnings and non-interactive error messages.

The value returned by each of these functions is initially implementation-defined, but can be dynamically bound; see with-standard-input, with-standard-output, and with-error-output.
(with-standard-input stream-form form*)  \rightarrow  \langle object\rangle  
(with-standard-output stream-form form*)  \rightarrow  \langle object\rangle  
(with-error-output stream-form form*)  \rightarrow  \langle object\rangle

These special forms first evaluate their stream-form argument to produce a stream $s$ and then evaluate their body forms in a dynamic environment where the corresponding function (standard-input, standard-output, or error-output) returns the stream $s$. The return value of each of these forms is the result of the evaluation of the last form of their body (or nil if there is none).

Example:

\begin{verbatim}
(with-standard-input (create-string-input-stream "this is a string")
  (list (read) (read)))
⇒ (this is)
\end{verbatim}

26.1 Streams to files

Streams might be connected to files or devices. Given a name, a stream can be created that is connected to a file having that name. File systems in which files are not named are not supported.

A filename is represented by a string. The correct syntax of filenames is implementation defined.

Streams to files are created by open-input-file, open-output-file, open-io-file, with-open-input-file, with-open-output-file, and with-open-io-file.

\begin{verbatim}
(open-input-file filename [element-class])  \rightarrow  \langle stream\rangle  
(open-output-file filename [element-class])  \rightarrow  \langle stream\rangle  
(open-io-file filename [element-class])  \rightarrow  \langle stream\rangle
\end{verbatim}

open-input-file opens a file for input only. open-output-file opens a file for output only. open-io-file opens a file for both input and output.

An error shall be signaled if filename is not a string. The corresponding file is opened in an implementation-defined way. These functions return an instance of the \langle stream\rangle class connected to the file specified by filename.

The element-class can be either the class \langle character\rangle (the default) or a positive integer that is a number of bits in a byte to be used for a binary stream. All implementations must support a value of 8 (denoting integer byte values from 0 to 255), but some implementations might support other byte sizes as well.

Note: When a binary stream is used, the order of bits within bytes and bytes within words (i.e., whether it is right to left or left to right) are each implementation defined.

Example:
(open-input-file "example.lsp" 8)  
⇒ implementation-defined

(with-open-input-file (name filename [element-class]) form*)  → <object>  
special operator
(with-open-output-file (name filename [element-class]) form*)  → <object>  
special operator
(with-open-io-file (name filename [element-class]) form*)  → <object>  
special operator

Each of these special forms opens a stream to a file (using open-input-file, open-output-file, or open-io-file, respectively), evaluates the forms, closes the file, and returns the value returned by the last form (or nil if there are no forms).

The filename and element-class are evaluated and passed as arguments to the appropriate file-opening function. The stream created by opening the file is bound to the variable named by name (as if a let was used), so the identifier name can be used to refer to the stream.

The stream is closed on exit, whether or not exit from these special forms is normal. For this reason, these special forms are usually preferred over the corresponding functions for opening and closing files.

Example:

(with-open-output-file (outstream "example.dat")  
  (format outstream "hello"))  
⇒ nil

(with-open-input-file (instream "example.dat")  
  (read instream))  
⇒ hello

(close stream)  → implementation defined  
function

The function close closes the stream stream. If stream is closed it may no longer be used in input or output operations. Closing a file stream ends the association between the stream and its file. If the stream was already closed this function performs nothing. The result value is implementation defined. An error shall be signaled if stream is not a stream (error-id. domain-error).

Example:

(defglobal input-str (open-input-file "data.lsp"))  
⇒ input-str

(close input-str)  ⇒ implementation-defined
(close input-str) => implementation-defined

(finish-output stream) -> <null> function

Completes any pending output to the destination designated by stream. Waits until the pending output is complete and then returns nil. For instance, pending output might be stored in a buffer; in this case finish-output forces the buffer to be written to the stream's destination. An error shall be signaled if stream is not a stream that can handle output operations (error-id. domain-error).

Example:

(defglobal output-str (open-output-file "data.lsp"))
  => output-str

(finish-output output-str) => nil

26.2 Other streams

Non-file streams can be created by the following functions:

create-string-input-stream  create-string-output-stream

A string stream is a stream that is simply a string. For input, the reading functions construct objects from a character sequence obtained from an input string. For output, the printing functions deliver characters which are collected to a result string.

(create-string-input-stream string) -> <stream> function

Creates and returns an input stream from the string. An error shall be signaled if string is not a string (error-id. domain-error).

Example:

(let ((str (create-string-input-stream "this is a string")))
  (list (read str) (read str) (read str)))
  => (this is a)

(create-string-output-stream) -> <stream> function
This function creates and returns a string output stream. The output to a string stream can be retrieved by \texttt{get-output-stream-string}.

\textbf{Example:}

\begin{verbatim}
(let ((str (create-string-output-stream)))
  (format str "hello")
  (format str "world")
  (get-output-stream-string str))
\Rightarrow "helloworld"
\end{verbatim}

\textbf{(get-output-stream-string stream) \to <string>} \textbf{function}

Returns a string containing all characters written to \textit{stream} since the last call to this function or since the creation of the stream, if this function has not been called with \textit{stream} before. An error shall be signaled if \textit{stream} is not a stream created with \texttt{create-string-output-stream} (error-id. \textit{domain-error}).

\textbf{Example:}

\begin{verbatim}
(let ((out-str (create-string-output-stream)))
  (format out-str "This is a string")
  (let ((part1 (get-output-stream-string out-str)))
    (format out-str "right!")
    (list part1 (get-output-stream-string out-str)))
\Rightarrow ("This is a string" "right!"
\end{verbatim}

\section{Input and output}

\subsection{Argument conventions for input functions}

Most of the reader functions that do input treat their arguments as follows:

When end-of-stream is reached (i.e., an attempt is made to read a stream element immediately after the last one in the stream), the behavior depends on the value of \texttt{co-s-error-p} (which defaults to \texttt{t}): if \texttt{co-s-error-p} is \texttt{nil}, the function returns the \texttt{co-s-value} (which defaults to \texttt{nil}); otherwise, an error shall be signaled (error-id. \textit{end-of-stream}).

If the \textit{input-stream} is not specified, the standard input stream (the value returned by the \texttt{standard-input} function) is used. An error shall be signaled if an \textit{input-stream} does not satisfy the \texttt{input-stream-p} predicate (error-id. \textit{not-an-input-stream}).
27.2 Character I/O

The following operations are used for character I/O. An error shall be signaled if an attempt is made to perform a character I/O operation on a stream that does not handle such operations.

\[
\text{read} \quad \text{[input-stream \ [cos-error-p \ [cos-value]]]} \rightarrow <\text{object}> \quad \text{function}
\]

The function \text{read} returns the ISLISP object that is created as the result of reading its textual representation from the stream \text{input-stream}.

See §27.1 for information about how \text{input-stream}, \text{cos-error-p}, and \text{cos-value} are treated.

Example:

\begin{verbatim}
(defglobal str (create-string-input-stream "hello #(1 2 3) 123 "\A")
  \Rightarrow str

(read str) \Rightarrow hello
(read str) \Rightarrow #(1 2 3)
(read str) \Rightarrow 123
(read str) \Rightarrow #\A
(read str nil "the end") \Rightarrow "the end"
\end{verbatim}

\[
\text{read-char} \quad \text{[input-stream \ [cos-error-p \ [cos-value]]]} \rightarrow <\text{object}> \quad \text{function}
\]

\text{read-char} reads a single character from \text{input-stream} and returns the corresponding character object.

See §27.1 for information about how \text{input-stream}, \text{cos-error-p}, and \text{cos-value} are treated.

Example:

\begin{verbatim}
(defglobal str (create-string-input-stream "hi")
  \Rightarrow str

(read-char str) \Rightarrow #\h
(read-char str) \Rightarrow #\i
(read-char str) an error shall be signaled
\end{verbatim}

\[
\text{preview-char} \quad \text{[input-stream \ [cos-error-p \ [cos-value]]]} \rightarrow <\text{object}> \quad \text{function}
\]

Returns the next character of \text{input-stream}, if any. The character is not consumed; the next attempt to peek at or read a character from the stream sees that same character.
See §27.1 for information about how input-stream, cos-error-p, and cos-value are treated.

Example:

```lisp
(let ((s (create-string-input-stream "foo"))
    (list (preview-char s) (read-char s) (read-char s)))
  \1\f \1\f \1\f
)
```

(read-line [input-stream [cos-error-p [cos-value]]]) → <object> function

 Reads a line of characters from input-stream and returns them as a string (without the newline character at the end of the line). If an end-of-stream is reached before the next newline character and a non-empty line has been read prior to the end-of-stream, that line is returned.

See §27.1 for information about how input-stream, cos-error-p, and cos-value are treated.

Example:

```lisp
(with-open-output-file (out "newfile")
  (format out "This is an example")
  (format out "%")
  (format out "look at the output file")
  \1\f
)
(defun str (open-input-file "newfile")
  \1\f
  (read-line str) ⇒ "This is an example"
  (read-line str) ⇒ "look at the output file"
)
```

(stream-ready-p input-stream) → boolean function

 Returns t if an attempt to obtain the next element from the stream will not cause the processor to have to wait; otherwise, returns nil. An error shall be signaled if stream is not a stream that can handle input operations (error-id, domain-error).

Example:

```lisp
(with-open-output-file (out "testfile.dat")
  (format out "This is an example")\1\f
)
(with-open-input-file (in "testfile.dat")
  (stream-ready-p in) \1\f
)
```
The function \texttt{format} has the side-effect of printing according to \texttt{format-string}. It returns \texttt{nil}. An error shall be signaled if the \texttt{output-stream} parameter does not satisfy the \texttt{output-stream-p} predicate (error-id. \texttt{not-an-output-stream}). An error shall be signaled if \texttt{format-string} is not a string (error-id. \texttt{domain-error}). The following is a summary of all the available \texttt{format} directives:

\texttt{obj} refers to the next item of the set of \texttt{obj*} to be processed.

\begin{itemize}
  \item [\texttt{~A}] Aesthetic: The \texttt{obj} is any object. \texttt{obj} is printed as it would with \texttt{~S}, but without escape characters. Characters are output directly without any conversion. That is, the output generated using this format directive is suitable for being read by a human reader.

  This effect is implemented by \texttt{(format-object output-stream obj nil)}.

  \item [\texttt{~B}] Binary: An error shall be signaled if \texttt{obj} is not an integer. \texttt{obj} is printed in binary radix (radix 2).

  This effect is implemented by \texttt{(format-integer output-stream obj 2)}.

  \item [\texttt{~C}] Character: An error shall be signaled if \texttt{obj} is not a character. \texttt{obj} is output directly without any conversion.

  This effect is implemented by \texttt{(format-char output-stream obj)}.

  \item [\texttt{~D}] Decimal: An error shall be signaled if \texttt{obj} is not an integer. \texttt{obj} is printed in decimal radix (radix 10).

  This effect is implemented by \texttt{(format-integer output-stream obj 10)}.

  \item [\texttt{~G}] General floating point: An error shall be signaled if \texttt{obj} is not a number. \texttt{obj} is printed as a float.

  This effect is implemented by \texttt{(format-float output-stream obj)}.

  \item [\texttt{~O}] Octal: An error shall be signaled if \texttt{obj} is not an integer. \texttt{obj} is printed in octal radix (radix 8).

  This effect is implemented by \texttt{(format-integer output-stream obj 8)}.

  \item [\texttt{nR}] Radix: An error shall be signaled if \texttt{obj} is not an integer. \texttt{obj} is printed in radix \texttt{n} (which must be between 2 and 36, inclusive).

  This effect is implemented by \texttt{(format-integer output-stream obj n)}.

  \item [\texttt{~S}] S-expression: \texttt{obj} is any object. This format directive outputs the textual representation of \texttt{obj}, with escape characters as needed. That is, the output generated using this format directive is suitable for input to the function \texttt{read}.

  This effect is implemented by \texttt{(format-object output-stream obj t)}.
\end{itemize}
"nT Tab: output enough spaces to move to column n (where column 0 represents the left margin). If already at or beyond column n, one space is output. If an implementation cannot determine the current column position, the behavior is implementation defined, but at least one space will be output. This effect is implemented by (format-tab output-stream n).

"X Hexadecimal: An error shall be signaled if obj is not an integer. obj is printed in hexadecimal radix (radix 16). This effect is implemented by (format-integer output-stream obj 16).

"% newline: output a #\newline character; This effect is implemented by (format-char output-stream #\newline).

"& conditional newline: output a #\newline character if it cannot be determined that the output stream is at the beginning of a fresh line; This effect is implemented by (format-fresh-line output-stream).

" " tilde: output a tilde (''). This effect is implemented by (format-char output-stream #\").

Example:

(format output-stream "No result") ⇒ nil
Output is: No result

(format output-stream "The result is ~A and nothing else." "meningitis")
⇒ nil
Output is: The result is meningitis and nothing else.

(format output-stream "The result i~C" #\s)
⇒ nil
Output is: The result is

(format output-stream "The results are ~S and ~S." 1 #\a)
⇒ nil
Output is: The results are 1 and #\a.

(format output-stream "Binary code ~B" 150)
⇒ nil
Output is: Binary code 10010110

(format output-stream "permission ~O" 493)
⇒ nil
Output is: permission 755

(format output-stream "You ~X ~X" 2989 64206)
⇒ nil
Output is: You BAD FACE

(progn
  (format output-stream "~&Name ~10Tincome ~20Ttax~X")
  (format output-stream "~A ~10T~D ~20T~D" "Grumpy" 23000 7500))
(read-byte input-stream [cos-error-p [cos-value]]) \to <integer> \quad \text{function}

Reads a byte from the input-stream and returns it. The number of bits in a byte is determined by the stream element type of the input-stream; see open-input-file.

See §27.1 for information about how input-stream, cos-error-p, and cos-value are treated.

Example:

;;; This example assumes 8-bit byte codes are stored in files.
(defglobal byte-example (open-output-stream "byte-ex"))
\Rightarrow \text{byte-example}

(format byte-example "hello") \Rightarrow \text{nil}
(close byte-example) \Rightarrow \text{implementation-defined}
(setq byte-example (open-input-stream "byte-ex" 8))
\Rightarrow \text{implementation-defined}

(read-byte byte-example) \Rightarrow 104 \quad \text{(implementation-defined)}
(read-byte byte-example) \Rightarrow 101 \quad \text{(implementation-defined)}
(read-byte byte-example) \Rightarrow 108 \quad \text{(implementation-defined)}
(read-byte byte-example) \Rightarrow 108 \quad \text{(implementation-defined)}
(read-byte byte-example) \Rightarrow 111 \quad \text{(implementation-defined)}

(write-byte z output-stream) \to <integer> \quad \text{function}
ISLISP Working Draft 22.0

Writes z to the output-stream and returns it. An error shall be signaled if z is not an integer in
the range appropriate to the stream element type of output-stream or if output-stream is not a
stream capable of handling output operations (error-id. domain-error).

Example:

(let ((out-str (open-output-stream "byte-example" 8)))
  (write-byte #b101 out-str)
  (close out-str))  ⇒ implementation-defined

28 Files

(probe-file filename) → boolean

Returns t if the file specified by filename exists; otherwise, returns nil. An error shall be
signaled if filename is not a string (error-id. domain-error).

Example:

(probe-file "notexist.lsp")  ⇒ nil
(defglobal new-file (open-output-file "notexist.lsp"))
  ⇒ new-file
(close new-file)  ⇒ implementation-defined
(probe-file "notexist.lsp")  ⇒ t

(file-position stream) → <integer>

Returns the file position associated with stream.

A file position is a non-negative integer that represents a position in the stream. For binary
streams, the file position represents the number of preceding bytes in the stream. It is increased
by one each time one of the following is done:

(read-byte stream)
(write-byte z stream)

For character streams, the file position is increased by an implementation-defined non-negative
amount each time one of the following is done:

(format stream...)

112  PUBLIC DOMAIN
(format-char stream char)
(format-float stream float)
(format-fresh-line stream)
(format-integer stream integer radix)
(format-object stream obj escape-p)
(format-tab stream column)
(report-condition condition stream)
(read-char stream)
(read-line stream)
(read stream)

The amount may depend on the output and on the file position itself. It is
implementation-defined which integer represents the first element of the file. An error shall be
signaled if stream is not a stream to or from a file (error-id. domain-error).

Example:

;;; This example assumes 8-bit byte codes are stored in files.
(desglobal example (open-output-file "example.lsp"))
⇒ example

(format example "hello") ⇒ nil
(close example)     ⇒ implementation-defined
(setq example (open-input-stream "example.lsp" 8))
⇒ implementation-defined

(file-position example) ⇒ 0 (implementation-defined)
(read-byte example)   ⇒ 104 (implementation-defined)
(file-position example) ⇒ 1 (implementation-defined)

(set-file-position stream z) ⇒ <integer>  function

Attempts to change the file position (see file-position) of the stream stream to z. If it is not
possible to move to the exact position z, some implementation-defined motion within the file
might still be performed. The value returned is the new file position, which might or might not be z.

An error shall be signaled if stream is not a stream to or from a file, or if z is not a non-negative
integer (error-id. domain-error).

Example:

(set-file-position example 4) ⇒ 4

(file-length filename element-class) ⇒ <object>  function
ISLISP Working Draft 22.0

Returns the length of the file named by filename, or returns nil if the length cannot be determined. The element-class determines the units. An error shall be signaled if filename is not a string (error-id domain-error).

Example:

(file-length "file27.dat" 8) ⇒ 25
;; Implementations are not required to support byte size 2.
(file-length "file27.dat" 2) ⇒ 100

29 Condition system

The condition system, sometimes called the “error system,” is a facility which permits problem situations detected at runtime to be represented and resolved while still under the control of a conforming program.

29.1 Conditions

When a problem situation is detected, a representation of that situation called a condition (or sometimes a “condition object” to emphasize its nature as an ordinary ISLisp object) is constructed and the situation represented by the condition is announced by a process called signaling. This signaling process allows a dynamically established handler an opportunity to resolve the problem.

Figure 1 shows an inheritance graph for the various condition classes.

Some condition classes require initialization arguments when using create so that associated data can be provided. For more information, see §29.3.

Conditions that represent situations involving dynamically detected program errors are called error conditions. Error conditions and those conditions that represent implementation limitations that may not be symptomatic of program errors are collectively called serious conditions.

Note: In some dialects of LISP a meaning is assigned to the idea of conditions that are not serious. Such conditions are beyond the scope of this document; hence the use of the class name <serious-condition> as the most general kind of condition defined herein.

29.2 Signaling and handling conditions

When a condition is signaled, the active handler is called with one argument, a condition which represents the situation. An initial active handler will have been established by the system; it will provide some implementation-defined action (such as return to toplevel, program exit, or entry into an interactive debugger). User programs may also establish handlers (see with-handler).
At any given time, only one handler is active. Establishing a new handler with `with-handler` shadows any previously active handler. This newly established handler is active throughout execution of its associated body of code unless shadowed by another use of `with-handler`.

If called, a handler function will execute in the dynamic environment of the call to `signal-condition`, except that the handler context is re-bound to match the dynamic handler state that was current at the point the handler function was established as the active handler.

**Note:** This means that handlers are not expected to handle errors in themselves. If a programmer wishes to have a handler handle its own errors, he might use `labels` to allow the function a way to refer to itself and might have the function re-establish itself as a handler within its own body.

When a handler is called, it must handle the condition by transferring control to a point outside of the call to `signal-condition`. Such a transfer of control might be made explicitly by use of `go`, `throw`, or `return-from` or implicitly by use of an abstract operation such as `continue-condition` that has an equivalent effect. The consequences are undefined if the handler returns normally; the handler is required to transfer control.

A handler may defer to previously established handlers by calling `signal-condition` on the condition object which it received as an argument.

### 29.2.1 Operations relating to condition signaling

\[
\texttt{(error error-string obj*) \rightarrow <object>} \quad \text{function}
\]

An error shall be signaled.

`error-string` and the `objs` are advice to the implementation about how the error message might be textually described (using `format`), but whether or not that advice is used is implementation defined.

This is equivalent to:

\[
\text{\begin{verbatim}
(signal-condition
 (create (class <simple-error>)
   'format-string error-string
   'format-arguments (list obj*))
 nil)
\end{verbatim}}
\]

\[
\texttt{(error continue-string error-string obj*) \rightarrow <object>} \quad \text{function}
\]

Like `error`, but the error that it signals is “continuable” (see `continue-condition`). The extra argument `continue-string` describes what happens if this function returns.

This is equivalent to:

\[
\text{\begin{verbatim}
(signal-condition
\end{verbatim}}
ISLISP Working Draft 22.0

```
(create (class <simple-error>)
  'format-string error-string
  'format-arguments (list obj*))
(let ((str (create-string-output-stream)))
  (format str continue-string obj*)
  (get-output-stream-string str)))
```

**(signal-condition condition continuable) → <object>**  
*function*

Invokes the condition handling system on *condition*.

If *continuable* is nil, the results of attempting to "continue" (see continue-condition) are not defined except that the call to signal-condition will not return normally.

If *continuable* is not nil, it will be possible to return from the call to signal-condition (see continue-condition). In this case, the specific value of *continuable* may be a string indicating the effect of continuing, or it may be the symbol t, indicating that an implementation-defined string such as "Continue with no special action." is to be used.

**Example:**

```
(signal-condition (create (class <simple-error>))
  'format-string "A ~A problem occurred."
  'format-arguments '(bad))
```

29.2.2 Operations relating to condition handling

**(ignore-errors form*) → <object>**  
*special operator*

Establishes a handler for <error>, such that if an error occurs during execution of *forms*, ignore-errors will immediately return nil. Then it executes *forms*, returning the value returned by the last *form* (or nil if there were no *forms*) if execution terminates normally.

**(report-condition condition stream) → <condition>**  
*generic function*

Presents a natural language description of *condition* to *stream*. This generic function may be specialized for user-defined condition classes.

**(condition-continuable condition) → <object>**  
*function*
Returns nil if condition is not continuable, or a string describing the effect of continuing otherwise.

(continue-condition condition [value]) transfers control and data  

“Continues” from condition by finding the call to signal-condition and arranging for it to perform a normal return of the value, which defaults to nil.

The consequences are undefined if the condition is not continuable.

(with-handler handler form*) → <object>  

Evaluates handler, which must yield a function (called the “handler function”). The handler function is established as active handler (see §29.2) and then the forms are executed. If execution of forms finishes normally, the value of the last form (or nil if there are no forms) is returned.

29.3 Data associated with condition classes

Some of the condition classes defined by ISLISP permit data to be associated with a condition object at its time of creation and later retrieved. Initialization arguments and accessor for such classes are defined here.

29.3.1 Arithmetic errors

<arithmetic-error> operation operation
operands operands
The operation is the function that was being performed, and the operands is a list of the arguments it received.

(arithmetic-error-operation arithmetic-error) → <function>  
arithmetic-error-operands arithmetic-error) → <list>  

These functions return the operation and operands supplied as data when creating the arithmetic-error. An error shall be signaled if arithmetic-error is not a condition of class <arithmetic-error> (error-kd. domain-error).

29.3.2 Domain errors

<domain-error> object object
expected-class expected-class
The object is the offending object, and the expected-class is the class that it was expected to be.
(domain-error-object domain-error) → <object>  function
(domain-error-expected-class domain-error) → <class>  function

These functions return the object and expected-class supplied as data when creating the domain-error. An error shall be signaled if domain-error is not a condition of class <domain-error> (error-id. domain-error).

29.3.3 Parse errors

<parse-error> string string
expected-class expected-class

The string is the string that was being parsed, and the expected-class is the class that the textual notation in the string was expected to represent.

(parse-error-string parse-error) → <string>  function
(parse-error-expected-class parse-error) → <class>  function

These functions return the string and expected-class supplied as data when creating the parse-error. An error shall be signaled if parse-error is not a condition of class <parse-error> (error-id. domain-error).

29.3.4 Simple errors

<simple-error> format-string format-string
format-arguments format-arguments

The format-string (a string) and format-arguments (a list of objects) are passed through to format to construct the error message. Each object in the list given as format-arguments becomes a separate data argument, obj, in the call to format.

(simple-error-format-string simple-error) → <string>  function
(simple-error-format-arguments simple-error) → <list>  function

These functions return the format-string and format-arguments supplied as data when creating the simple-error. An error shall be signaled if simple-error is not a condition of class <simple-error> (error-id. domain-error).

29.3.5 Stream errors

<stream-error> stream stream

The stream is the stream on which the error occurred.
(stream-error-stream stream-error) → <stream> function

Returns the stream supplied as data when creating the stream-error. An error shall be signaled if stream-error is not a condition of class <stream-error> (error-id. domain-error).

29.3.6 Undefined entity errors

<undefined-entity> name name
namespace namespace

The name is a symbol representing the identifier which was undefined. The namespace is one of the symbols variable, dynamic-variable, function, or class.

(undefined-entity-name undefined-entity) → <symbol> function
(undefined-entity-name-space undefined-entity) → <symbol> function

These functions return the name and namespace supplied as data when creating the undefined-entity. An error shall be signaled if undefined-entity is not a condition of class <undefined-entity> (error-id. domain-error).

The result of undefined-entity-name-space will be one of the symbols variable, dynamic-variable, function, or class.

29.4 Error identification

The following is a summary of all named errors in the language and the semantics associated with each error.

- **arity-error**: Errors of this kind occur when a function is activated with a number of arguments that is not compatible with the number of parameters permitted by the function’s definition. Errors of this kind are represented as conditions of class <program-error>.

- **cannot-create-array**: Errors of this kind occur when a request is made to allocate an array that cannot be allocated. Errors of this kind are represented as conditions of class <storage-exhausted>.

- **cannot-create-cons**: Errors of this kind occur when a request is made to allocate a cons that cannot be allocated. Errors of this kind are represented as conditions of class <storage-exhausted>.

- **cannot-create-list**: Errors of this kind occur when a request is made to allocate a list that cannot be allocated. Errors of this kind are represented as conditions of class <storage-exhausted>.

- **cannot-create-sequence**: Errors of this kind occur if a function that produces a sequence (e.g., subseq) cannot allocate that sequence. Errors of this kind are represented as conditions of class <storage-exhausted>.
<table>
<thead>
<tr>
<th>Condition</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cannot-create-string</td>
<td>Errors of this kind occur when a request is made to allocate a string that cannot be allocated. Errors of this kind are represented as conditions of class <code>&lt;storage-exhausted&gt;</code>.</td>
</tr>
<tr>
<td>cannot-create-vector</td>
<td>Errors of this kind occur when a request is made to allocate a vector that cannot be allocated. Errors of this kind are represented as conditions of class <code>&lt;storage-exhausted&gt;</code>.</td>
</tr>
<tr>
<td>cannot-parse-number</td>
<td>Errors of this kind occur when the string parameter received by the parse-number function cannot be classified as the textual representation of a number. Errors of this kind are represented as conditions of class <code>&lt;parse-error&gt;</code>.</td>
</tr>
<tr>
<td>control-error</td>
<td>Errors of this kind occur when an attempt is made to leave a block more than once or when there is no outstanding catcher for a catch tag. Errors of this kind are represented as conditions of class <code>&lt;control-error&gt;</code>.</td>
</tr>
<tr>
<td>division-by-zero</td>
<td>Errors of this kind occur when an attempt is made to divide by zero. Errors of this kind are represented as conditions of class <code>&lt;division-by-zero&gt;</code>.</td>
</tr>
<tr>
<td>domain-error</td>
<td>Errors of this kind occur when the object given as argument to a standard function for which an argument class restriction is in effect is not an instance of the class to which the argument is restricted. Errors of this kind are represented as conditions of class <code>&lt;domain-error&gt;</code>.</td>
</tr>
<tr>
<td>end-of-stream</td>
<td>Errors of this kind occur when an attempt to read a character or byte at the end-of-stream when eos-error-p argument is true, or when an attempt to read a more complex object is about to begin (e.g., by read or read-line) but the end-of-stream is seen before parsing of that object has finished. Errors of this kind are represented as conditions of class <code>&lt;end-of-stream&gt;</code>.</td>
</tr>
<tr>
<td>immutable-binding</td>
<td>Errors of this kind occur when an attempt is made to change an immutable binding. Errors of this kind are represented as conditions of class <code>&lt;program-error&gt;</code>.</td>
</tr>
<tr>
<td>improper-argument-list</td>
<td>Errors of this kind occur when the last argument given to the apply function is not a proper list. Errors of this kind are represented as conditions of class <code>&lt;program-error&gt;</code>.</td>
</tr>
<tr>
<td>index-out-of-range</td>
<td>Errors of this kind occur when the index given to a function that accesses an element in a sequence (such as elt) is an integer outside the range of the sequence. Errors of this kind are represented as conditions of class <code>&lt;program-error&gt;</code>.</td>
</tr>
<tr>
<td>not-an-input-stream</td>
<td>Errors of this kind occur when an attempt is made to read from a stream which is not an input stream. Errors of this kind are represented as conditions of class <code>&lt;domain-error&gt;</code>.</td>
</tr>
<tr>
<td>not-an-output-stream</td>
<td>Errors of this kind occur when an attempt is made to write to a stream which is not an output stream. Errors of this kind are represented as conditions of class <code>&lt;domain-error&gt;</code>.</td>
</tr>
<tr>
<td>unbound-variable</td>
<td>Errors of this kind occur when an attempt is made to access an unbound variable. Errors of this kind are represented as conditions of class <code>&lt;unbound-variable&gt;</code>.</td>
</tr>
</tbody>
</table>
undefined-entity Errors of this kind occur when the entity denoted by an identifier does not exist when an access to that entity is made. Errors of this kind are represented as conditions of class &lt;undefined-entity&gt;.

undefined-function Errors of this kind occur when a function does not exist at its activation point. Errors of this kind are represented as conditions of class &lt;undefined-function&gt;.

Some errors that can occur have not been named in this document, and others might be added by the implementation. The above list should not be taken as an exhaustive list of all possible errors in the language.

30  Miscellaneous

(identity obj) → &lt;object&gt; function

Returns an object that is the same as obj under eql. obj may be any ISLISP object.

Example:

(identity '(a b c)) ⇒ (a b c)

(get-universal-time) → &lt;integer&gt; function

Returns an approximation to the “current time” in Universal Time Format. The units are seconds. Universal Time Format represents time as an integer number of seconds since the beginning (i.e., midnight), January 1, 1900 UT (ignoring leap seconds). If get-universal-time is called twice, the first value shall be less than or equal to the second value.

No implementation is required to have a way to verify that the time returned is correct. However, an error shall be signaled if an implementation can determine that the time it would return would not be correct (e.g., it can determine that the clock was never initialized).

Example:

(get-universal-time) ⇒ 2901312000

(get-internal-run-time) → &lt;integer&gt; function

(get-internal-real-time) → &lt;integer&gt; function
get-internal-real-time returns as an integer the current time in \textit{internal time units}, relative to an arbitrary time base. The difference between the values of two calls to this function is the amount of elapsed real time (\textit{i.e.}, clock time) between the two calls.

get-internal-run-time returns as an integer the current run time in \textit{internal time units}. The precise meaning of this quantity is implementation defined. The difference between the values of two calls to this function is the amount of time between the two calls during which computational effort was expended on behalf of the executing program.

\begin{verbatim}
(internal-time-units-per-second) \rightarrow \langle\text{integer}\rangle
\end{verbatim}

\textbf{function}

\texttt{internal-time-units-per-second} returns the number of time units per second for the implementation.
